FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

I. GENERAL INFORMATION

AGRICULTURE VICE MINISTER OUTLINES PREMISES FOR FUTURE DEVELOPMENT

Hong Kong CHING-CHI TAO-PAO [ECONOMIC REPORTER] in Chinese No 6, 15 Feb 82 pp 16-17

[Article: "Situation and Trends in China's Agriculture. China's Deputy Minister of Agriculture, Liu Ruilong [0491 3843 7893] Replies to Questions From This Journal's Reporter"]

> [Text] Editor's Note: In this article, China's deputy minister of agriculture, Liu Ruilong, mostly explains and elaborates on three main questions (in reply to questions from this journal's correspondent) as follows: (1) Development of China's agriculture has entered a new historical stage of development and the situation is very good, but development is unbalanced. (2) Hastening of the development of agriculture requires, first, reliance on policies and, second, reliance on science. (3) What is meant by Chinese style agricultural modernization.

The Transformation of Rural Villages and the Situation in Agriculture

Question: Please tell us the situation in China's agriculture.

Answer: Following the Third Plenary Session of the 11th Party Central Committee, China readjusted its rural policies and corrected the "leftist" errors of the past. It conducted necessary readjustment of production relationships, and restructured the organization of labor, the method of remuneration, and farming methods. It destroyed the former situation of over centralization of management, blind guidance in production, egalitarianism in distribution, eating out of a "common pot," and various inequitable burdens. It established and perfected various forms of a system of responsibility for production, took firmly in hand development of economic diversification, effectively aroused the enthusiasm of the broad masses of peasants, and impelled China's agriculture toward a new period of historical development.

Question: What are the main indications that China's agricultural situation is very good?

Answer: The main indication is all around increase in outputs. The area sown to grain last year was 50 million mu less than two years ago, and quite a few provinces sustained severe natural calamities; nevertheless, total grain output achieved the levels of the previous year, making it the second highest year for output since the founding of the People's Republic. Output of cotton, oil-bearing crops, and sugar increased over 2 years ago, and other economic crops, and sugar increased over 2 years ago, and other economic crops were able to exceed or fulfill plan. Steady growth took place in the livestock industry, outputs of hogs, cattle, sheep, and goats increasing. Commune and brigade enterprises continued progress in the midst of reorganization. Both forestry and the fishing industry also had new growth. Peasant income increased; life improved further, and in an appreciable number of areas that have long been poverty stricken, the problem of having enough to wear and getting enough to eat has been solved. The overall situation in rural villages today is political stability, economic prosperity, contented production, worry free production, and diligent production. This is a fundamental change.

However, we have noted that development of the rural situation has not been balanced, that the foundation for agriculture has not been consolidated, and that we are a considerable distance away from being "over the hump." Consequently sustained and steady agricultural development will require great efforts.

Question: What are the favorable factors in sustained and steady development of China's agriculture?

Answer: After 3 years of readjustment new trends and new factors have emerged in China's rural villages that are beneficial for agricultural development.

First, the enthusiasm of both the collectives and individuals has been aroused, and a situation has come about in which the collective, individuals, and the state are all moving upward together. This is a basic element in the sustained and steady development of agriculture. Factors advantageous to development of agriculture in the peasant family economy, in particular, things such as cooperative efforts among families, private plots, small amounts of peasant family funds, and small farm implements were formerly restricted in the role they would play. Now, however, they have been emancipated and are playing an increasingly larger role. Individual welfare and collective welfare are closely combined, and arousal of individual commune member enthusiasm is closely linked to the full play of superiority of collective unit farming, which are our most fundamental experiences in the development of agriculture since founding of the People's Republic. During recent years, the various rural policies of party and government have stressed adherence to the principle of voluntary participation and mutual benefit with the object of arousing these two enthusiasms.

Second, China's agriculture is moving away from the singular role as a grain growing industry to which it has been limited to economic diversification, with all around development of farming, forestry, livestock raising, sideline occupations, and the fishing industry. People have gradually come to realize that all around development helps make full use of China's abundant workforce resources and natural resoruces, helps make the most of multiple economic benefits in every field, helps provide more agricultural byproducts for society, helps enliven the economy, and helps the stable and healthy development of agriculture as a whole.

Third, peasant enthusiasm for the study of science and the application of science is being raised. Regions in which farming had formerly been done in a careless way are now developing in the direction of intensive farming, and the level of intensive farming in high yield areas is continuing to rise. During the past 3 years, the area sown to grain throughout the country has declined by more than 100 million mu, yet grain output increases year by year. Cotton output also increases year by year. This is the result of intensive farming, which has raised yields per unit of area.

Fourth, accompanying development of economic diversification has been an increase in agricultural byproducts, increasing peasant prosperity, expansion of exchanges of goods between cities and the countryside, and rather rapid development of city and rural collective commerce and individual businesses that function to agument state owned and collectively owned businesses. Production of rural goods and exchanges of goods are now in process of surmounting obstacles to win further development.

Development of Agriculture Through Reliance on Policies and Science

Question: In his work report to the National People's Congress, Premier Zhao Ziyang noted that acceleration of agricultural development requires reliance on policies and science. What are your views on this?

Answer: This is the summation of many years experience. The state intends gradually to increase investment in agriculture, but it cannot be very much. Consequently development of agricultural production and moving forward with rural construction requires continued reliance on policies and on science. This is because both hold an extremely huge potential. Reliance on policies and on science holds the hope and the potential for future development of agriculture in China, and is also the object of our efforts.

Question: Please explain the significance of reliance on policies.

Answer: Many years experience, particularly the experiences of the past 3 years, attest that correct policies have played an outstanding role in arousing enthusiasm among the broad masses of peasants. We firmly believe that among the broad masses of peasants exists an extremely great enthusiasm for socialism. The peasants demand adherence to the path of socialist collectivization of agriculture, and support public ownership of the means of production such as land. The peasants call for readjustment of production relationships and institution of various forms of a system of responsibility for production, and in so doing do not divorce themselves from socialism or the socialist system of public ownership. Rather, they demand elimination of the influence of past "leftist" errors of overcentralization, blind guidance, egalitarian "eating out of a large common pot," and inequitable burdens of various kinds that fettered them. Therefore, when the party responds to the demands of the broad peasant masses, guarantees and respects the autonomy of production teams, institutes various forms of a system of responsibility, and develops economic diversification, the enthusiasm of the broad masses of peasants rises rapidly. The State Council has already made clear that adherence to the path of socialist collectivization and the system of public ownership of the means of production such as land will remain unchanged for a long period of time, and adherence to the practice of systems of responsibility for production in the collective agricultural economy will not change for a long time. Efforts will be made to improve upon and perfect the various forms of a system of responsibility for agricultural production and various rural economic problems. On the issue of systems of responsibility in agricultural production, the principles of "adaptation of general methods to local situations and tailored guidance" must be upheld to permit diverse forms. In addition, it is necessary that all quarters also give attention to improving the economic benefits of agricultural production.

Question: In what areas has state support to agriculture been manifested?

Answer: First, in protection of the peasants' vested interests, in stable policies, in not lightly changing effective prevailing economic policies.

Second, in guaranteeing the use in agriculture of state investment in agriculture, with no diversion to non-agricultural purposes.

Third, in guaranteeing to supply the means of production and the means of livelihood, in opening numerous channels for trade, in planned development of collective rural businesses, in operating rural free markets, and in enlivening exchange of goods between cities and the countryside, the products produced by the peasants thereby being converted to commodities, and the industrial products required by or used in the daily life of rural villages being able to satisfy demand.

Fourth, in vigorous development of the small farm implements and hand tools so urgently needed in rural villages, and improvement in production of tools and semi-mechanized tools to satisfy peasant needs. Readjustment of inequitable use of nitrogenous, phosphate, and potash fertilizers through increase in phosphate and potash fertilizer production.

Question: Please also explain the significance of reliance on science.

Answer: Use of modern agricultural science and technology to equip agriculture, and putting agricultural production techniques and economic management on a scientific foundation are prerequisites for accelerating development of agriculture and promoting the modernization of agriculture. Premier Zhoo's report provided a consummate explanation of this. The goal in reliance on science by agriculture is to have China's agriculture take the path of small investment for fairly high economic benefits. In order to do this, we have to place research on and spread of agricultural science and technology in a major position, linking the fruits of modern scientific and technical research to China's superior tradition of intensive agriculture, to wrest from nature the large amounts of agricultural products we require.

Chinese Style Modernization of Agriculture

Question: In his government work report, Premier Zhoo Ziyang noted that simultaneous with development of the entire agricultural economy must be consideration of and provisions for rural construction. What are your views on this?

Answer: I believe that across the board consideration has to be given agricultural production, rural construction, and the peasants' livelihood. This involves the entire agricultural process, i.e. it includes the three-part needs of agricultural production's preliminaries, production itself, and follow-up. Preliminaries include improvement in conditions for agricultural production, equitable arrangements for workforces, and supply of the means of production. Production itself includes the science and technology and management methods needed for production in farming and livestock raising. Follow-up includes processing, storage, transportation, commodity exchange, banking, and credit involved for agricultural pyproducts. Secondly, consideration must be given the total livelihood needs of the peasants, most notably their needs for food, clothing, shelter, items needed in daily life, travel, education, and personal cultivation. In this way, consideration can be given both to production and to livelihood. In addition, rural construction and building of the national economy as a whole must be considered together. I believe that rural construction should provide good conditions both for agricultural production, and provide good production conditions and living conditions for agricultural producers and residents of rural areas, and should, at the same time, provide good conditions for development of the national economy as a whole, and for equitable distribution and deployment of productive forces. To this end, for development of the needs of agricultural production and for the needs of rural village people's livelihoods, a combination of building of rural material civilization and spiritual civilization, plus coordination with needs for development of the national economy as a whole, and all around planning of rural construction is very necessary.

Question: What is the program for development of China's agriculture?

Answer: Our program is active development of economic diversification without any let up whatsoever in production of grain. The first requirement is equitable use of existing cultivated land, plus a determination to make gradual, equitable, and full use of mountains, hills, grasslands, rivers, lakes, ponds, coastal beaches, and sea areas, plus greater all around development of the rural economy to assure comprehensive growth of the national economy. This is also the fundamental strategy under present circumstances for development of China's agriculture.

Question: What problems should China watch when studying longterm development needs of agriculture?

Answer: We must take a Chinese style path of modernization, and walk the path of socialist modernization of agriculture. We are determined to walk a new path of comparatively rapid economic development, comparatively good economic results, and greater material benefits for the people. This is the total basis for our future planning.

Second, we must also assimilate our own experiences. We must purposefully study foreign science and technology and advanced economic management methods of use to us. However, we positively cannot repeat or adopt for use the tortuous roads and inherent maladies of others. The so-called "energy intensive agriculture" requiring high investment and high energy consumption to derive agricultural products that is practiced abroad creates serious environmental pollution and lopsided development, which we should be careful to avoid.

Third, agricultural development in all countries faces common requirements, but there is no common model. The so-called common requirements are modernization of technological equipment, scientific production techniques and management methods, and socialization and specialization of labor engaged in production. However, progress in development of agriculture differs from country to country, and we cannot rigidly copy the various different models. Therefore, we must formulate, on the basis of China's own situation, the long range plans and the various programs and policies for agricultural development.

Question: What is the substance of China's situation?

Answer: Deputy Chairman Chen Yun made a penetrating capsulization of China's situation, namely that a series of characteristics ensue from having "a population of 1 billion, 800 million of whom are peasants." In terms of China's agriculture as a whole, this results in two basic characteristics: One is a small average per capita amount of cultivated land, but numerous mountains, water surfaces, vast grasslands, and fairly abundant natural resources. Second is antiquated technical facilities, but abundant workforce resources. Development of China's rural economy must, therefore, proceed from these realities.

Question: What is Chinese style modernization of agriculture?

Answer: By the so-called Chinese style is meant setting the goals, policies, steps to be taken, and emphasis of development of China's agriculture on the basis of China's natural resources, economic foundation, technological level, and on the basis of needs of national economic and agricultural development. Thus the Chinese style modernization of agriculture has to proceed from China's circumstances and requirements, use modern science and technology and socialist industry to equip agriculture with two kinds of public ownership, put agricultural production technology and economic management on a modern, scientific footing, build an equitable agricultural economic structure, and production pattern, and a fine cyclical agricultural ecological system, build a flourishing agriculture with all around development of farming, forestry, livestock raising, sideline occupations and fisheries, and prosperous rural villages in which agriculture, industry, and commerce are integrated so as to derive highly developed land productivity rates, labor productivity rates, commodity rates, and employment rates. Modernization of China's agriculture is also a process of economic development and technical reform. As Premier Zhao said in his report, China's workforce resources are abundant, but capital is inadequate; for a fairly long time to come, there can be no total demand for reliance on new technology or a lopsided seeking after automation. Thus, the relationship between modern science and technology and China's fine traditions will have to be handled well to modernize China's traditional techniques and to Sinify modern foreign science and technology.

SEVERAL NEW RICE VARIETIES DESCRIBED

Beijing NONGCUN CONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 12, 5 Dec 81 p 23

[Article by Zeng Sui [2582 4482] and Huang Zhongyin [7806 0022 8337]: "Introduction of Several Superior Rice Varieties"]

[Text] Chaogui

Chaogui is a superior variety bred by the Guangdong Provincial Academy of Agricultural Sciences. Plant height is about 100 centimeters; stems are sturdy; leaf color is dark green; root system is well developed; absorption power is strong; adaptability in fertile fields is fairly broad; proness to close rows in the early stage of growth; high light energy utilization rate and light content [0342 0698] efficiency rate. Panicles are large and numerous; grains are heavy; colony structure is good; and per thousand weight of grains is about 25 grams.

Weaknesses are: Poor disease resistance. Grown as an early crop, prone during early and late stages to blast of rice, rice neck blast, and bacterial blight. Grown as a late crop, prone during the early and late stages to red bacterial blight and bacterial blight. Poor tolerance of cold, of drought, and of heat. In growing Chaogui, comprehensive prevention and control measures have to be taken. In areas in which blast of rice, bacterial blight, and natural disasters frequently occur, it should not be grown.

Hong 410

Hong 410 is an early ripening high yield superior variety bred by the Tongan Superior Variety Farm in Fujian Province. This variety has short, thin stems; colony structure is good; tillering is strong; leaf color is dark green; root system is well developed; panicles are short; heads are numerous; effective panicles number between 300,000 and 350,000 per mu, each panicle contains about 60 grains; grains are plump; and the per thousand grain weight is 28 grams. Weaknesses are a low rate of polished rice and fairly poor rice quality. It is fairly sensitivie to temperatures, and will not tolerate low temperatures between the booting and panicle formation stages. It shows poor resistance to disease, being prone to rice blast, sheath and culm blight, and purple stem [4793 4427] blight, the incidence rate of which is rather severe. It is also prone to rice stem borer, leaf roller, and leafhopper infestations.

Guangluai No 4

Guangluai No 4 is a superior variety successfully bred by the Guangdong Provincial Academy of Agricultural Sciences. Plant height of this variety ranges from 80 to 85 centimeters; stems are thick; leaf blades somewhat broad, short and thick; and leaf color is dark green. During the seedling stage, it tolerates cold; its tolerance of drought is strong; it tolerates fertilizer and resists lodging; has a high tillering and panicle formation rate; and grows evenly. Fruiting rate is generally around 90 percent; the paddy is round and plump; per thousand grain weight is about 26 grams; polished rice rate is high; and polished rice quality is intermediate. Weaknesses include too premature degeneration when grown in places where the water table is high or the soil heavy. Its requirements for fertilizer are large, and in addition to sufficient base fertility, it requires heavy applications of fertilizer, with early tillering fertilization to promote early and rapid growth. It is prone to yellow dwarfing and bacterial blight, and is also subject to leafhopper and rice stem borer infestations against which timely prevention and control work must be done.

Late Crop Aigeng 23

Aigeng 23 is a late ripening late geng variety bred by the Zhejiang Provincial Academy of Agricultural Sciences. Plant heights range from 85 to 90 centimeters; plants are rather compact; growth is delicate; structure of stems and leaves is equitable, light being able to penetrate directly to the base of plants; the root system is well developed; making for absorption of water and fertilizer; stems are tough and tensile; it is tolerant of fertilizer and resistant to lodging; it may be close planted, and it shows fairly strong resistance to bacterial blight. Panicles are between 14 and 16 centimeters long; grains cluster fairly closely together; per thousand weight of grains is about 25 grams; and polished rice rate is between 82 and 85 percent. Its weaknesses include proness to rice blast, necessitating intensification of of preventive measures in seedling beds and open fields during the seedling stage, and it is prone to leafroller and aphid infestations.

Early Rice Qingganhuang

Qingganhuang is a late rpiening early xian variety bred by the Zhejiang Provincial Academy of Agricultural Sciences through the crossing of Guangluai No 4 with Longge 16. Plant height is about 78 centimeters; plants are compact; leaf color is light green; seedlings grow evenly; tolerance of cold is fairly strong; each panicle contains about 65 grains; fruiting rate is approximately 82 percent; per thousand grain rate is 22 or 23 grams; and it shows fairly great flexibility in fertility requirements. When grown under conditions of medium to low fertility, extent of yield increase is fairly great; when grown under conditions of adequate fertility, it is better able to make the most of its potential for increased yields. Its weaknesses are fairly weak tillering strnegth, necessiting provisions for closeness in transplanting and increased number of transplanted clumps so that numbers of panicles and numbers of grains will be accordingly regulated. It is fairly prone to brown leaf blight, which requires intensification of fertilizer and water management, controlling the amount of nitrogenous fertilizer given in the late stage. When disease is spotted, pesticides must be used at once to control it.

Zhongdan No 2

Zhongdan No 2 is a new rice variety bred by the Crop Institute of the Chinese Academy of Agricultural Sciences in cooperation with the Dandong Agricultural Institute in Liaoning Province. The seedling age requirements of this variety are not strict; plants are compact; plant height runs from 100 to 105 centimeters; stems are tough and tensile; resistance to lodging is strong; panicles are 22 centimeters long, each panicle containing about 120 grains, the per thousand grain weight of which is 27 grams. It is strongly resistant to blast of rice and medium resistant to bacterial blight. It is early ripening; widely adaptable; has a high polished rice rate, with rice of good quality, the polished rice rate being 82 to 83 percent. Its shortcoming is fairly weak tillering strength. When transplanting seedlings, one must be sure to maintain a basic number of seedlings.

PRESENT, FUTURE ROLE OF RURAL ENTERPRISES DISCUSSED

Hong Kong CHING-CHI TAO-PAO [ECONOMIC REPORTER] in Chinese No 6, 15 Feb 82 pp 18-19

[Article: "Rural Enterprises Have Achievements to Their Credit--Interview With Deputy Minister of Agriculture Du Ziduan [2629 1311 4551]"]

> [Text] Editor's Note: China has 1.43 million commune and brigade enterprises producing more than 10,000 different products. Their estimated output value in 1981 was 68 billion yuan, and they played a major role in the national economy. Inasmuch as commune and brigade enterprises have numerous characteristics, they have vast prospects for future development.

During the past several years, commune and brigade enterprises in China's farflung villages have prospered to become a major force in China's national economy and a powerful support for consolidating development of the rural collective economy. By way of understanding the current situation in rural enterprises, the correspondent recently interviewed Du Zirui, deputy minister of agriculture and director of commune enterprises.

Remarkable Achievements From Readjustment of Rural Enterprises

Deputy Minister Du said that China's rural commune and brigade enterprises have developed on a foundation of the rural collective economy, and have been founded and developed little by little from disbursements of funds from commune member collective accumulations. Because they fit in with the orientation of overall rural economic development, development has been fairly rapid and now commune and brigade enterprises in the country number 1.43 million.

These enterprises produce a great variety of wares, principally small farm machines and tools, chemical fertilizer, pesticides, cement, coal, construction materials, foodstuffs, handicrafts, and processed goods from farming, forestry, animal husbandry, and fisheries; They also are concerned with fruit orchards, tea groves, the raising of livestock and poultry, hatching of aquatic products, construction, and transportation and communications. In 1980 commune and brigade enterprise products numbered more than 10,000 different kinds.

Dr Zirui said that along with the readjustment and restructuring of the national economy done during the past 2 years, commune and brigade enterprises have also carried out reorganization, their structure gradually becoming more rational. Those plants in competition with large industries for raw materials have turned to the production of other goods. Labor-intensive industries, particularly agricultural byproduct processing industries and service trades, have developed very rapidly, and production of consumer goods has increased strikingly while the ratio of other trades and industries has gradually declined. In 1980, commune and brigade enterprise total earnings grew by 42.8 percent as compared with 1978 earnings of 43 billion yuan. The ratio derived from processed industrial raw materials and fuels feel from 44 percent to 39.8 percent, and electro-mechanical products dropped from 25.3 percent to 22.6 percent. Earnings from construction and service trades rose from 18.6 percent to 21.1 percent, and agricultural products processing industry earnings went from 11.1 percent to 16.4 percent.

Remarkable advance was made in the restructuring of commune and brigade enterprise organization and the emergence of more than 20,000 jointly operated enterprises of various kinds. More than 2,000 commune and brigade enterprise supply and marketing companies have been established at all levels, and numerous communes have established supply and marketing administration units, warehouses, and retail outlets. Enterprise administration and management is in process of improvement, and the labor productivity rate has risen 30 percent since 1978.

Currently, commune and brigade enterprises' total output value, total earnings, and fixed assets each account for one-third in the rural collective economy. In 1980, total income for the year amounted to 61.4 billion yuan, a 22 percent increase over 1979. During the first half of 1981, it again increased by 10.4 percent over the same period during the pervious year.

Rural Enterprises Play Major Role in Collective Economy

Deputy Minister Du said that commune and brigade enterprises, no less than farming and livestock raising, are an important integral part of the rural economy. Development of rural enterprises plays a major role in the transformation of the backward state of rural villages and in the prospering of the national economy. China has a large rural population living on a relarively small amount of cultivated land. Its commodity economy is not well developed, and peasant earning levels are low. Experience has shown that development of rural enterprises holds clear advantages for solution to the following problems:

Accumulation of Funds for Development of Agriculture. Between 1978 and 1980, income from rural enterprises, in addition to being a source of 7.6 billion yuan in funds for the expansion of reproduction and support of agriculture (3.3 billion going for capital construction of farmlands, 3.2 billion being used to purchase farm machinery; and 1.1 billion being used to support poor brigades) was used to run collective welfare enterprises in rural villages for culture, education, and health.

A Money Tree For Peasants Increases in Income. A 1980 survey showed that in 90 percent of somewhat more than 5,500 of the most prosperous production brigades operated brigade enterprises. In some places, commune and brigade enterprises have become the principal source of peasant income. In 10 suburban Shanghai counties, half of peasant earnings derived from collective sources in 1980 was from commune and brigade enterprises. In 1980, 65 percent of the average per capita distribution of 182 yuan from the collective to peasants in suburban counties of Beijing derived from commune and brigade industries and sideline occupations.

Provided For Large Quantities of Labor Surplus to Agriculture. With the increase in the extent of agricultural mechanization and steady improvements in the system of responsibility for production, more and more surplus labor appeared in China's rural villages. Development of rural enterprises is a major road for providing jobs for this surplus labor. Today peasants employed throughout the country in commune and brigade enterprises number 30.5 million, or 10 percent of the total rural workforce. In places in which commune and brigade enterprises have developed rapidly, as for example in suburban Shanghai counties, the labor force engaged in industry rose from 15.7 percent in 1976 to the present 23.2 percent. Development toward division of labor and division of industries for the rural workforce and the economic structure is an inevitable trend in development of the modern agricultural economy.

Impetus to Building of Small Rural Cities and Towns. China's rural areas have more than 53,000 small market towns. Accompanying the commune and production brigade operation in small market towns of fabrication industries, agricultural products processing industries, businesses, food and beverage service industries, cultural and amusement activities, and such enterprises and public facilities, has been the preliminary formation in 20 percent of market towns of small new cities and towns combining the characteristics of city and country, industry and agriculture. Commune and brigade enterprises have a 3 million man construction corps that produces all manner of building materials that has created conditions for a transformation in the building of small cities and towns, and in rural dwellings.

Has Become a Major Integral Part of China's Industry. In 1980, output value of rural industries amounted to 10 percent of China's total industrial output value. Of the industrial products produced by rural enterprises, coal accounts for 17 percent of the nation's total output, phosphate fertilizer for 37 percent, chemical pesticides for seven percent, cement for eight percent, bricks and tile for 75 percent, silk knit goods for 14 percent, and about 80 percent of drawnwork, embroideries, bamboo, rattan, willow, and grass plaited articles, and small farm tools. Output value of commune and brigade food industries. Rural enterprises in the suburbs of large cities such as Beijing, Shanghai, and Tianjin also contract to provide spare parts or perform processing for a large number of large enterprises, becoming indispensable assistants to large industries. For example, 63 percent of Shanghai's production of clothing is processed by commune and brigade enterprises. Thirty percent of the parts used to make the famous Eternal and Phoenix brand bicycles are provided by commune and brigade enterprises and by plants jointly operated by industry and agriculture.

Has Increased the State's Fiscal Revenues. In 1980, commune and brigade enterprises paid 2.6 billion yuan in taxes to the state. Government revenues in 10 Shanghai suburban counties increased by 14 percent between 1979 and 1980, 61 percent of these revenues deriving from commune and brigade enterprises.

Vast Prospects for Development of Rural Enterprises

Deputy Minister Du Zirui said that for China to reach a "comfortable level" by the end of this century, it will be necessary to permit four-fifths of the country's peasant population to gradually become prosperous, which will require hastening the speed of development of rural enterprises. At the National Agricultural Work Conference convened by the Ministry of Agriculture not long ago, experts discussed the problem of hastening commune and brigade enterprise development, and formulated a development plan for the sixth 5 year plan. On the basis of a year by year increase in total earnings from commune and brigade enterprises calculated at 68 billion yuan in 1981, earnings of more than 100 billion were envisaged for 1985 for a 67 percent increase over 1980.

He said China has numerous advantageous conditions for the development of rural enterprises. About one-third the nation's surplus workforces are in rural villages. Resources that can be developed for use are abundant. The market is vast. Development of agricultural (including livestock) production, economic diversification, and family sideline occupations can provide large amounts of capital and raw materials. Some state own industries want to enter into joint operation with commune and brigade industries for mutual advantages.

Du Zirui noted that commune and brigade enterprises themselves possessed strengths. They are widely dispersed in rural villages where they can use resources that large industries cannot use. They are small in scale, the proportion of their hand operations being large, and they can adjust to changes in market demands and make timely readjustments in the orientation of their products. They require little investment of capital; results are fast; that they are strongly competitive. "These advantageous conditions and characteristics" demonstrate that commune and brigade enterprises have vast prospects for development in China.

PROBLEMS IN ASPECTS OF LAND RELATIONSHIPS OUTLINED

Beijing ZIRAN BIANZHENGFA TONGXUN [JOURNAL OF DIALECTS OF NATURE] in Chinese
No 6, 81 pp 16-20

[Article by Yu Guangyuan [0060 0342 6678]: "Study of National Land Economics" (continuation)]

[Text] 3. The 24 Aspects of 12 Pairs of State Land Relationships

I intend to present here problems in 24 aspects of 12 pairs of national land relationships. 1. Plains and mountains. 2. Dryland and water surfaces. 3. Drylands and oceans. 4. Large plots and odd pieces. 5. Above ground and below ground. 6. Developed and undeveloped. 7. Readily used and hard to use. 8. Northern and southern. 9. East and west. 10. Rural villages and cities. 11. National land and public land. 12. Partial and total. A total of 24 aspects of 12 pairs. Two aspects of each pair require close attention, but I plan to lay comparative stress on the latter aspect. Of course, this is not to say that the former aspect need not be looked at carefully. Moreover, when there are several pairs, it is not possible to distinguish which deserves emphasis.

The first problem, plains and mountains.

Ours is a country with many mountains. The area of mountains, plains and hills, taken together, cover more than 6.3 million square kilometers, amounting to 66 percent of the national land area. More specifically, mountains account for 59 percent, plains for two percent, and hills for 12 percent. Among the large countries of the world, China has a large ratio of mountainous land. The mountainlands of the USSR occupy only 10 percent of its land area, and only about 15 percent of America's. China's mountainlands also have shortcomings. One is that they are high. Mountains more than 1,000 meters above sea level and high plains account for 57.9 percent of the national territory, those above 2,000 meters accounting for 32.9 percent of this. Differences in elevation are also great. At the same time, generally speaking, their soil layer is fairly poor, and the ecological system fairly brittle. But the total area is vast, and in a fairly large portion of mountain areas, conditions are very good. The semi-tropical and tropical mountain and hill regions south of the Chang Jiang, for example, have abundant water resources and biological resources. In northern mountainlands too, forestry and animal husbandry can be developed. For a long time China has attached more importance to flat land (and this is as it should be), but has attached less importance to mountainlands. As a result, the potential in China's mountainlands is very great. To take a case in point, I recently walked around for an entire day in the Mentougou area of Beijing. From east to west and from west to east, I traversed a region in which numerous mountain tops had no trees. It was not until I had gone the way into the western landscape that there were some changes. Beijing Municipality's statistics show that output value of Beijing forestry is only one percent of total output value of agriculture, and that total output value of Beijing's agriculture accounts for only five percent of total output value of Beijing's industry and agriculture. The result of the two multiplied together is that Beijing's forestry output value (including timber and dry tea), amounts to only .05 percent. Moreover, the mountain area of Beijing Municipality amounts to 62 percent of its more than 26,800 square kilometers. I feel these figures are able to demonstrate that the situation in development of mountainlands for use is very poor. A systematic study of mountainlands use should be initiated.

The second problem, dryland and water surfaces.

China had about 400 million mu of inland waterlands--180 million mu of rivers, 120 million mu of lakes, and 100 million mu of reservoirs and ponds. Use of the country's water surfaces is somewhat different than its use of mountain regions, and this is because 92 percent of the water surfaces are distributed southeast of a line running from Qionghun to Lanzhou to Tengchong. They are in regions of China that are fairly well developed economically and where population is fairly dense. However, the situation in use of China's fresh water surfaces is by no means good. Catches from freshwater have declined from 470,000 tons in 1959 to 300,000 tons in 1979. Though the reasons are diverse, failure to attach full importance to use of water surfaces is the main one. As a result of the emphasis on taking grain as the key link for a period of time to the neglect of economic diversification, water surfaces have shrunk by more than 20 million mu, and up until not long ago, two-thirds of fresh water surfaces where fish could be easily raised were not well used. Water surfaces not very well used include reservoirs. Since the founding of the People's Republic, more than 81,000 reservoirs, large and small, have been built, those providing water surfaces suitable for the raising of fish covering 30 million mu. Last year at the national technological and economic academic discussion conference on all around use of reservoirs, enthusiastic discussions took place among delegates on problems of raising fish in reservoirs. To get an idea of the potential of China's water surfaces, all that is necessary is a comparison of two different water surfaces whose natural states are very similar. Some lakes can produce more than 200 jin per mu while others produce only 1 or 2 jin per mu. In choice pools, yields reach more than 3,000 jin per mu. With good management, yields per mu from water surfaces need be no less than yields per mu of agricultural land.

The third problem, dryland and oceans.

China is not only a large continental country; it is also a large maritime country. In studying the economic of China's national territory, not only should serious attention be given development and use of national territory on land, but development and use of the oceans should also be studied. China faces the sea to the east and south, and has a continental coastline that is 18,405 kilometers long, not including the length of the coastline of offshore islands. China's seas (including Bohai, the Yellow Sea, The East China Sea, and the South China Sea) total 4.73 million square kilometers in area. People who study marine economics are rather fond of using the concept of a coastal belt. By this is meant an area extending landward for 10 kilometers from an average line along the shore touched by the waters of the sea, and extending seaward from the same line to a water depth of 20 meters. This area is called the coastal belt. Coastal belt and coastal waters are different concepts. The concept of a coastal belt is suited to economic study. The concept of an economic zone is applied internationally to an ocean area extending outward for 200 kilometers. China covers more than 40 degrees latitude from south to north and has very great differences in climatological, hydrological, and geological conditions. Its seas abound in biological resources, and they are also a huge storehouse of marine mineral resources. However, out development of the seas is backward as a result of historical reasons. Old China was basically unable to exercise its sovereignity over the seas. Though this has now changed, economic techniques are still backward, and ocean resources cannot be well developed or used. In studying China's territorial economy, the sea area, which is more than two-fifths the area of all its land, requires the attention of an extremely large force. The quantity of ocean catches should be greatly increased, and ocean hatching should be done. Production of ocean mineral resources should be developed, and possibilities for use of ocean energy resources should be studied. We have much to do in these regards.

The fourth problem, large plots and odd pieces.

I intend that odd bits of land not be looked down on. Beside fields, beside roads, beside homes, beside rivers, beside this, and beside that are odd bits and pieces of land. Each individual piece seems very small, but when all the bits and pieces in the country are put together, it amounts to a great amount. If well used, it can solve large problems. Most of these bits of land are in densely populated areas, which means places where land is very valuable, making its use very important. If, for example, the soil grew pasture grass rather than weeds, or were it planted to something like false indigo that could be used for many purposes, greater economic benefit would be gained from it. False indigo, for instance, has a fair amount of protein in it, and is good for preparing industrial animal fodder. Use of industrial methods to produce synthetic animal fodders can effect a saving in half of the amount of grain used, and poultry and livestock that are fed synthetic livestock fodder grow very well, the amount of lean meat in pork amounting to slightly more than otherwise. Even with weeds, if they are cut and fed to milk goats, that constitutes a good way of producing too. Goats milk is rich, and has more nutrients than cows milk. Odd bits of land may also be used to raise earthworms or ground beetles.

With regard to forestry, I have always advocated use of odd bits of land, including those in cities, for large scale planting of trees. In 1978, I envisaged planting trees in Beijing in every place where trees could be planted. I believe that substantial benefits would derive from so doing. The planting of trees where people live and in cities could both help solve the problem of residents' needs for lumber, and could reduce destruction of mountain forests. It is a way of killing two birds with one stone.

The fifth problem, above ground and below ground.

I intend to talk about the problem of mineral resources under this heading. These are of four major kinds. One is inorganic solid minerals; one is organic minerals metamorphosed from ancient organism; one is water; and one is geothermal energy and others. Some of these mineral resources are on the surface of the ground and some are underground; some are buried deep, and some are buried shallow. China's mineral resources are very abundant. This is because mineral production forms a direct ratio with land area. It is also because China's resources have not been well developed; numerous ores lie sleeping beneath the ground. This state of affairs differs greatly from the situation in developed countries. When talking about minerals, one particularly must talk about energy. Since China is a mountainous country, and the mountains are high, water energy resources are particularly abundant, but the utilization situation is particularly poor. Some countries have an 80 to 90 percent utilization rate of their water power resources, but in China the rate is a surprising less than three percent. Unless water energy resources are used, a large amount of energy annually will flow east and south into the oceans. Energy like this that is not used is lost forever, unlike the organic minerals that have been metamorphosed from ancient plants and animals. These resources are extremely limited and 1 ton used means 1 ton less. To regard petroleum and coal only as energy sources is also not to look at them in a comprehensive way. They are also raw materials for the chemical industry and should be more used as raw materials for the chemical industry. Thus, they should be particularly cherished. This is my point of view. As regards problems of the moment, in order to race against time and hurry up, and in consideration of capital and results, this view will require concrete verification. I feel with regard to China's mineral resources that to say only that the land is vast and minerals abundant, or to say only that resources cannot be considered abundant in terms of population is not to be complete. Both aspects must be talked about. On the one hand, one must realize that abundant resources are one of China's strengths; on the other hand one must realize that our resources cannot be considered great. We must particularly value our own resources.

The sixth and seventh problem, the developed and the undeveloped, and the readily used and hard to use.

I have economized here by not writing the words national territory. If there is any plot of land in the country that has not been developed, that is possibly because the soil is difficult to use; however, undeveloped land is not necessarily land that is hard to use. Historical conditions, economic conditions, and geographic location all play a role in development or lack of development. The undeveloped soil of China still amounts to quite a bit, and some of it is in places where natural conditions are extraordinarily good. I feel that the term "develop" has been used too little for a long time in the past. This term should be used henceforth in places where it should be used to strengthen our concept of development. Development of the land in an area is a major matter, and one that possitively cannot be undertaken helterskelter. Development work, must be done well from the very beginning. If it is not done well at the outset, a passive situation may ensue for a long time. Not long ago I paid a visit to Japan where I traveled in Hikkaido. I learned that 110 years ago Hokkaido was still a region of scant population inhabited by minority peoples. It was a place to which the government of Japan sent criminals. Only 110 years ago the decision was made to develop this region, and in the short space of time until today, it has been built up to what it now is. One must say that they were very successful in their work of developing Hokkaido. The Japanese government's experiences in developing Hokkaido merit our emulation. Once they decided to develop Hokkaido, they set up a government organization for the development of Hokkaido in February 1869. One of the major actions taken by this organization was to operate a school. Not long after deciding to develop Hokkaido, a school was opened in Tokyo in 1872 for the development of Hokkaido (Colonization Office Temporary School). Three years later, this school moved to Sapporo, Hokkaido where its name was changed to "Sapporo School of Agriculture." As I understand it, operation of this school was, in one sense, for study of technical measures for the development of Hokkaido, particularly agricultural measures. In another sense it was to train cadres for the development of Hokkaido. This school was operated entirely on public funds. Those who studied hard were also sent abroad for advanced work. But there was one condition, and that was that once their studies were over, they had to serve on Hokkaido for 5 years after which they could freely elect employment. These students studied what was necessary for Hokkaido, and an overwhelming majority of them settled down on Hokkaido to become mainstays in the development of Hokkaido. In 1907, this school's name was changed to "Agricultural College of Northeast Imperial University," and in 1917 it was again changed, this time to "Hokkaido Imperial University." In 1949, this was changed to "Hokkaido University," and it continues in operation until this day. I believe this use of science and education to blaze a trail is a good method. It is a method that encourages developers to forge ahead.

Inasmuch as we want to develop quite a few areas, it is extraordinarily necessary to seriously study development plans. While summarizing China's experiences and lessons of other countries.

Lands that can be readily used should be used to the full. National territory that is hard to use will require study of methods and steps to be taken on the basis of conditions in order to use it. Strictly speaking there is no land that cannot be used. Barren land and places with no trace of human beings can be used for purposes requiring barren land and places with no trace of human beings. Atomic bomb experiments cannot be carried out in places teeming with people. In all the world there is no such thing as land that cannot be used, but only land that is difficult to use. Discovering uses for land that is difficult to use, and finding ways and means of using national territory that is difficult to use is a major task of the study of national land economics.

The eight and ninth problems, south and north, east and west.

The north and south, east and west problems here means China's internal problems as distinct from north and south, east and west international relations.

China's internal problems of relationships between eastern regions and western regions are problems in relationships between fairly well developed regions and fairly undeveloped regions. Population is dense in the eastern part of the country; transportation is convenient; and the terrain is relatively low. In the western part of the country, population is sparse; transportation is inconvenient; and terrain is very high. The entire Tibetan high plateau averages more than 4,000 meters above sea level. For historical reasons, customs and habits, and degree of culture also shows extensive differences. There are two different regions for which there should be two different national land programs for development and use, preservation and administration. Our study of the western regions is currently comparatively weak, yet it is precisely this region that can take large numbers of China's population. In terms of nationality relationships, the east is inhabited largely by the Han nationality, while the west is where national minorities live.

Unlike international north-south problems, though China's south and north have some differences in the extent of their development, this is not their major distinguishing characteristic. In the north and northeastern regions, heavy industry is very developed. The coastal region of the north is also a developed region. In China, climatic conditions are a major point of difference between south and north. The north is dry while the south get copious rainfall. Great differences also exist in minerals. The region with the most abundant coal resources, for example, is the north, in Shanxi, Nei Monggol, and the Northeast. In the southeastern and south central region, coal is lacking. Efforts to divert northern coal to the south have not met with success. Problems between south and north include problems in distribution of labor between south and north, and problems in cooperation between south and north.

The tenth problem, cities and rural villages.

Inasmuch as the national land of which we are talking includes national land that has already been transformed by human activities, the land of rural villages and cities constitutes not only a foundation, but when taken together with structures on the land, also belongs to the concept of national land. In the study of national land economics, we must attach importance both to rural villages and to cities. In rural villages where people are engaged in agriculture, forestry, and animal husbandry etc, national land economic problems exist. The urban economy also takes land. It has a geographical position on national land problems of rural villages, in addition to land required for production is land required for construction of dwelling sites, rural road construction, and such problems. Rural construction requires clear guiding ideas and must be planned. China's rural construction is very important. The current situation in which rural villages take up good farmland merits very much attention, one of the reasons being a blindness in use of land. Prior to the war against Japan, some bourgeois scholars formed a "rural construction faction," which in terms of its ideological bent and political bent was antithetical to the anti-imperialist, anti-feudal revolutionary movement led by our Communist Party. Where we called for revolution, they advocated reform. Now that we are carrying our socialist construction, we need numerous people who are enthusiastic for rural construction, both old people and young people. Now we ought to have a rural construction faction with a lot of people in it—a socialist new village construction faction. We need people enthusiastic about the study of rural villages, about how to make production develop, about how to improve living standards, about what is the most suitable way for people in different regions to build houses, about what kinds of construction materials to use, about what the design of dwellings should be, about what fuels are most suitable, about how general use of methane can become a reality; about the degree to which electrification should be achieved in a given period of time, about how to solve problems in rural roads and rural transportation, about requirements for rural culture, education, and sanitation, about how rural services should be developed...all these things require concern. In China today, 80 percent of the population lives in rural villages and the problem of rural villages construction is an extremely important one. In order to do this job well, fairly great improvements will have to be made in rural village construction, so that people will be at ease about rural village conditions. Life in a rural village has inconveniences of many kinds, and no particular attention is given politics or work. That young people are not content in rural villages is a very big problem. Means must be found to solve it. Right now, one not very good situation is that all eyes look toward the cities. People in society cannot be entirely blamed for this. This has to do with our situation in many of its aspects and with our work. Were life in rural villages not so much inferior to life in cities, people would not look toward the cities. This also has something to do with some of our prevailing systems and policies. For example, regional wage scales were set on the basis of price differences in various places in the period immediately following Liberation. Subsequently prices became the same in all areas, but very great differences in wages continued. As a result, the more poverty stricken a place, the less concern for standards of living. Some comrades have told me that living subsidies in the Xining region of Qinghai Province are higher than in the much more poverty stricken Muangzhong region. This is a policy question. When policies are not set properly, people do not want to go to rural villages, and this is extraordinarily bad for our construction of rural villages. We should make our policies encourage youth to find contentment in rural villages or find contentment in border regions.

The foregoing has talked about rural villages, but problems in urban construction also require a loud cry of warning. The formation and development of cities is an inevitable tendency in economic development. In the building of socialism, all around consideration must be given to what kind of cities are to be built on our national land, their location, their size, their characteristics, and the orientation of their development. We have to do a good job of population spread and, most important in this regard, is planned facilities in cities. Right now we do not have such plans, and no one is responsible for conducting studies of this kind. We do not advocate blind development of large cities, but without relevant planning, this problem cannot be fundamentally solved. Strict control over the flow of population into large cities cannot, by itself, solve the problem any more than it has in the past. Going from rural residential areas to small towns, to county seats or to small cities that are the equivalent of county seats, going to medium size cities, to large cities, or to exceptionally large cities such as Shanghai and Beijing requires a total conception. This is also one of the most important tasks in national land economics.

In addition is urban construction itself. For planning work in this regard, there are indeed people and organizations responsible. However, in a period of more than 30 years, not even in the capital city has a plan been presented to the inhabitants. In this regard, work is China also lags behind that of numerous countries in the world. In urban construction per se lie problems in equitable use of national land. For example, how should homes of residents be designed so as to make most equitable use of land; how should the problem of land to supply vegetables to urban areas be solved; and what liaison should be established between large cities and rural villages are all problems to be considered.

The eleventh question is national land and public land.

Public land is a term I made up. I use this term to mean land that does not belong to any country, or land that is the public property of all the countries of the world. High seas is a term that everyone is in the habit of using; however, the world's public lands consist of more than just the high seas. Antarctica is also publicly owned. Space beyond a certain number of kilometers, I fear, has not been, as yet, designated as belonging to the country directly beneath it. Therefore, it is best to use the term public land to mean that empty land on the globe that does not belong to any country. Since it is public land, all that is needed is the strength for us, like other countries, to make use of it. This is our right, and one that we should be concerned about. For example, the tracks followed in space by synchronous communications satellites are limited. Unless we take possession of a certain position, somebody else will occupy it.

The twelfth question, partial and total.

In the foregoing we talked of the problem of this portion of national land and that portion of national land. In modern society, close intercourse exists between people living in this portion of the national land and that portion of it. A lot of transportation of goods takes place, and there is also a rapid exchange of information so that all of society has become a totality. Numerous problems about national land economics will be solved in the realm of the country as a whole. So national land problems are closely related to communications problems (including electrical communications). Development plans for part of national land are also closely related to development of the land of the entire country.

It has been national land itself that has been discussed in these 12 problems. The second part discussed problems of national land classification, national land and the ecology, national land and population, and national land and communications. In this way I have covered most of the topics that have occurred to me. Our task is to carefully investigate these problems and to get a large amount of material about them, as well as to carry out a penetrating study to arrive at scientific conclusions. Our task is a large one requiring good organization of existing forces. In addition, it is necessary to plan large scale training of people for this purpose. Today, though the organs of state power in China are huge, those we need are still lacking. One example is a national land renovation management organization, which is still in process of formation. China's various intellectual organizations are not complete and are relatively weak. In handling the issue of intellectual organizations, we should not use the same methods used to handle organs of national power. The former should be streamlined, while the latter also has to oppose a situation of an inordinate number of incompetent people. However, specialized talent with genuine knowledge should be given opportunity to make full use of their skills and change the present situation that can be generally termed weak.

There is nothing mysterious about building a new field of knowledge. Looked at in terms of numerous fields of knowledge, there is a fundamental guiding idea. In the building of a field of knowledge, methodology is a consideration after which comes steady work, steady accumulation, the writing of books and reports to establish a body of knowledge. Many have been established whose importance and whose foundation are far less than that of the field of national land economics. Much less do they have the large quantity of survey materials for a foundation that this branch of learning has, or the assistance of numerous neighboring fields of learning. All of us are very enthusiastic, and the Chinese National Land Economics Research Society has been established. In addition, socialist construction has urgent need of this field of learning, and the work of managing national land and renovating national land has been placed on the agenda of the party and the state. The branch of learning of national land economics, I believe, can be smoothly established.

NEW EMPHASIS GIVEN YIELDS PER UNIT OF AREA IN RESTRUCTURING OF AGRICULTURE

Fuzhou FUJIAN RIBAO in Chinese 1 Jan 82 p 1

[Article: "Total Output Value of China's Agriculture Increases More Than 15 Percent in Three Years. Readjustment of Internal Structure of Agriculture and of Crop Patterns Wins Fine Achievements"]

[Text] China's readjustment of the internal structure of agriculture and of crop patterns has won fine achievements. Despite frequent national diasters during the past 3 years in which grain output has risen rather than fallen, the total output value of agriculture has increased at a five percent rate annually. Comparison of 1981 with 1978 shows an increase of about 15 percent.

According to data from each province submitted to higher authority, a comparison of 1981 with 1978 shows a reduction by more than 100 million mu in the national area sown to grain, but an increase by more than 30 billion in grain output nevertheless, making it the second highest year for grain output since the founding of the People's Republic. In 1981, outputs of cotton, oil-bearing crops, and sugar crops increased by 31, 80, and 32 percent respectively over 1978. Outputs of mulberry cocoons, tea, and flue-cured tobacco increased by 44, 21, and 12 percent respectively. Such tremendous increases in output of these economic crops has been rarely seen since founding of the People's Republic. Only jute and amberi hemp among the economic crops have declined in area sown, their outputs falling, this the result of development of artificial fiber production. The livestock industry, forestry, and aquatic products have also steadily increased in output or output value. In 1981, hog, cattle, sheep and goat total outputs increased more than 38 percent over 1978. Commune and brigade enterprises showed healthy development. Commune household sideline occupations were filled with vitality, and home poultry raising reached all-time highs.

With the equitable readjustment of the internal structure of agriculture and of crop patterns, agriculture not only provided the state greater amounts of processed raw materials, enlivened city and country markets, and strengthened the collective economy, but also improved the lives of the peasants. In poverty stricken regions with a population totaling 150 million, in particular, improvements in the lives of the masses was even more spectacular. Today, a new situation of political stability, economic prosperity, and peace of mind pervades the rural villages of the country. Commune members say that now policies are good; there is enough to eat; people are content; and zeal is high.

Readjustment of the structure of agriculture began in the wake of the Third Plenary Session of the 11th Party Central Committee.

Today all jurisdictions are acting in accordance with the program put forward by the CCP Central Committee and the State Council for "active development of economic diversification with positively no relaxation in grain production" to formulate plans for readjustment of the structure of agricultural production, which are characterized by the following: Maintaining generally stable the present ratio of grain and economic groups grown, but giving greater attention to increased yields per unit of area to increase total output. The future focus of readjustment will be on development of mountain regions, water surfaces, and grasslands, as well as on improvements in the ecological environment, on equitable use of all the land of the country, and further implementation of the party's policies in development of economic diversification for the good of both the collective and individuals. In short, it is intended that efforts over a not very long period of time will gradually build an economically diversified and comprehensively developed equitable production structure in China's agriculture. In this way our avenues will become ever broader, and the agricultural situation will become increasingly better.

AFFORESTATION DRIVE GATHERS MOMENTUM

OW141145 Beijing XINHUA in English 1223 GMT 12 Mar 82

[Text] Beijing, 12 Mar (XINHUA)--Workers and cadres across China, including Beijing's first Communist Party Secretary Duan Junyi and Mayor Jiao Ruoyu today involved themselves in a national tree-planting drive in response to a government greening campaign. The first secretary and the mayor planted trees in Lianhuachi, a Southwest Beijing park.

In the past few days, Shanghai government, party and army leaders each planted three trees while forestry specialists in the capital campaigned in the streets to promote the drive. Fifty of them set up a booth in Beisd's downtown area selling popular science books, pictorials and journals on afforestation and prevention of tree pests and answering all kinds of questions concerning the subject.

Trees are being planted on the dykes of the Yellow River in Henan and Shandong provinces while in Inner Mongolia, 26 counties have agreed on forestry quotas. Northern Jiangsu Province's Xuzhou Prefecture, often victimized by floods, drought and sandstorms, has incorporated its tree-planting plan into its overall farmland improvement program.

Provincial leaders in Jiangsu, Hunan, Fujian and other provinces, have taken the lead in this drive. Since late January's spring festival holiday, Xu Jiatun and other officials in Jiangsu have planted 1,200 pines, metasequoia, sweet-scented osmanthus trees and 20,000 box trees.

Together with other government functionaries and 500 gardeners, Hunan officials have planted 2,000 camphor, sassafras and other trees on the scenic Yuelu hills near Changsha. Fujian officials have afforested a Fuzhou park. Anhui Province's Hefei city government has set afforestation quotas and targeted sections of land to be planted by its subordinate offices. Factories, offices, schools and army units in Jinan, Shandong Province, have also been asked to participate.

In cities with insufficient tree saplings, manpower, materials and funds have been channeled into improvement of tree and grass nurseries and flower gardens.

Officers and soldiers of the People's Liberation Army will plant trees within 10 kilometers of their barracks. Soldiers in Wuhan helped plant trees along streets and scenic areas in the past 2 months while frontier guards in Guangxi joined border residents in afforesting barren mountains.

The P.L.A. Beijing units will contribute 130,000 workdays to the afforestation effort.

TREND OF LIVESTOCK INDUSTRY DEVELOPMENT DISCUSSED

Hong Kong CHING-CHI TAO-PAO [ECONOMIC REPORTER] in Chinese No 6, 15 Feb 82 pp 20, 25

[Article: "Development of China's Livestock Industry and International Cooperation--Interview With Deputy Minister of Agriculture Cai Ziwei [5591 1311 0251]

> [Text] Editor's Note: China and Australia have cooperated in setting up at Nanshan in Hunan Province the Nanshan demonstration pastureland on an area of 420 hectares. China has cooperated with New Zealand to establish at Liabin County in the Guangxi Autonomous Region the 1,200 hectare Qianjiang demonstration pastureland. Using free assistance given by the United Nations Development and Plans Office, the Food and Agriculture Organization invited experts to guide the building of a demonstration pastureland in Wengniute Banner, Nei Mongol on which construction has already begun. In June last year, the International Agricultural Development Fund signed a long term low interest loan agreement for 35 million yuan with China.

Last October, the Ministry of Agriculture convened the National Agricultural Work Conference in Beijing. One of the main topics of the conference was the summarization and exchange of experiences during the past several years in the rapid development of China's livestock industry, with discussion as to how to further hasten the speed of development of the livestock industry today and during the period of the sixth 5 Year Plan. After the conference, the correspondent interviewed the deputy minister of agriculture responsible for the livestock industry, Cai Ziwei, asking him to give a briefing on the development of the livestock industry.

Recent State of the Livestock Industry and External Cooperation

Cai Ziwei said that the present development of China's livestock industry is such as has been rarely seen in the more than 30 years since the founding of the People's Republic. This is manifested principally in the following: An increase in the quality of various kinds of livestock and poultry, and a gradual increase in various kinds of livestock products; achievements in the improvement of livestock and poultry, some superior varieties having been successfully bred; increase in international exchange and cooperation in the livestock industry.

Following 2 years of all around development of China's livestock industry, the growth trend continued to be maintained last year. In 1980, total output of beef, pork, and lamb [or goat] for the country was 24.1 billion jin, a 7 billion jin increase over 1978, the all time high in China's history. During the first half of last year, 92 million head of live hogs were removed from the country's inventory, an increase of 850,000 head over the same period during the previous year.

At the end of 1980, the number of large herbivorous animals in inventory including cattle, horses, donkeys, and mules numbered 95.25 million head, a 660,000 head increase over the previous year. As of the end of last June, the number showed a 1.02 million head increase over the same period two years ago. In 1980 there were more than 17.4 million more sheep and goats than in 1978, and at the end of last year, 187.31 million of them were in inventory. The raising of rabbits, particularly long haired rabbits, developed very quickly in many places. An estimated more than 200 million rabbits are being raised throughout the country.

In 1980, China's sheep wool output was 351.46 million jin, a 45.12 million jin increase over 1979. Goat hair output stood at 8.01 million jin, a 9.5 percent increase over the previous year. During the first half of last year, the state purchased 193.73 million jin of wool, 5.16 million jin of goat hair, and 6.61 million jin of rabbit fur, a 16, 8, and 54 percent increase respectively over the same period two years previously.

During the past 3 years, extent of increase in output of poultry eggs nationally has been greater.

Improvement in livestock and poultry varieties in China is going along smoothly. Success has been achieved in the breeding of superior varieties of beef cattle. During the 1970's, China introduced nearly 20 different breeds of cattle from abroad. Following breeding to improve varieties, the number of fine breed beef cattle and combination milk and beef cattle now being raised in the country now stands at more than 2 million head. The flesh of fine breed beef cattle is tender in quality and delicious in taste. During the past 3 years, almost 200,000 tons of it has been exported to Hong Kong and Macao where it has been enthusiastically received by consumers. Striking increase in exports again took place last year. In recent years China has established beef production bases in 140 counties where fine breed beef cattle will continue to be grown in future.

China has also had new achievements in the breeding of fine breed fine wool sheep. An average of between 6 and 7 kilograms of fine wool is sheared annually from each mature ewe of this fine sheep breed, the fineness of wool being mostly 64 count, and the rate of clean wool being 50 percent. Within 12 months, the wool reaches a length of from 9 to 10 centimeters. Wool quality is good; it contains lanolin, and is characterized by great curliness. The Ministry of Agriculture is presently vigorously promoting the growing of this fine breed of fine wool sheep in Xinjiang, Nei Monggol, and Jilin.

Deputy Minister Cai said that the increase in livestock and poultry and the increase in livestock products had increasingly enlivened city and country markets in the country, and the supply situation was gradually improving. Great increase has also taken place in foreign exchange earnings resulting from the export of livestock products. In 1980 foreign exchange earnings from the export of livestock products amounted to $1.85 billion, a $320 million increase over 1979. China remained world champion in quantities exported of hog bristles, hog intestines, sheep skin, honey, rabbit fur, and rabbit meat.

The scale of China's technical exchange with foreign countries and international cooperation in the livestock industry has expanded year by year. In cooperation with Australia, China established a 420 hectare Nanshan demonstration pastureland at Nanxhan in Hunan Province. In cooperation with New Zealand, Zealand, the 1,200 hectare Qianjiang demonstration pastureland was established in Laibin County in the Guangxi Autonomous Region. Gratis support given by the United Nations Development Plans Office enabled the Food and Agriculture Organization to invite experts to give guidance in the establishment of a demonstration pastureland in Wengniute Banner in Nei Monggol. Work on these projects began in December 1979, January 1980, and in March.

In June last year, the International Agricultural Development Fund signed a longterm low interest loan agreement for 35 million yuan with China, and the "China's Northern Grassland and Livestock Industry Development Project" formally became effective. China is now designing and planning the use of these preferential loan funds to try to establish a prototype of Chinese style modernization of the livestock industry.

New Changes in the Livestock Industry During the Period of Readjustment

After providing a briefing on China's accomplishments in the livestock industry during the past 3 years, Deputy Minister Cai Ziwei pointed to new changes during the past several years in the field of China's livestock industry as demonstrated in the following four ways:

One is the liberalization of policies, the emancipation of productivity, the elimination of restrictions on peasant raising of livestock and regulations of various kinds prohibiting the raising of livestock and poultry, revival of market trade and livestock trading markets, and the appearance in many places of the country of an upsurge in the peasant raising of hogs, cattle, sheep and goats, rabbits, and chickens. Formerly few peasants privately raised cattle, but in 1980 the number reached 8.66 million head, or 12.2 percent the total number of cattle in the country. In places with facilities for the processing of milk products, commune member raising of milk cows has developed especially rapidly.

The appearance of a group of key households, and specialized households engaged in the raising of livestock and poultry, is a new phenomenon in China's development of the livestock industry.

Second is the gradual implementation of systems of responsibility, which has brought about the consolidation and developmnnt of state livestock breeding farms and livestock pastures giving a new lease on life to the collective livestock industry economy. The systems of responsibility for production practiced in pastoral regions today are not the same in name, in substance, or in character; yet they do have common characteristics, The means of production (meaning mostly livestock and the grasslands) substantially adhere to a system of public ownership; egalitarianism has been surmounted in distribution, which embodies, in varying degrees, the principle of distribution in accordance with work. Specialized contracting, the linking of remuneration to output, and practice of such various forms of a system of responsibility for production has meant that numerous hog, cattle, sheep and goat raising farms have been able to convert losses into gains, individuals getting more, the collective earning more, and the exchequeur deriving more revenues. In 1980, total national output value of livestock breeding farms was 278.46 million yuan, a 103 percent increase over 1979.

Third is readjustment of the structure of farming and livestock industry structure and of the internal structure of the livestock industry, which has won results. In many places during the past several years, the livestock industry has developed rapidly, the livestock industry increasing its proportion of the local economy. Output value of the livestock industry in the country as a proportion of total agricultural output value climbed from 13.1 percent in 1978 to 14.2 percent in 1980. Increase in herbivorous animals such as cattle, sheep, goats, and rabbits, was fairly rapid. The proportion of cows and ewes in herds increased, and the survival rate from breeding increased.

Fourth, more and more farmers and herdsmen give attention to selection of breeds, the formulation of feeds, and prevention and control of epidemic diseases. They conscientiously study and burrow into science and technology and the practice of scientific animal husbandry. The former situation in which number of head of cattle in inventory was the sole pursuit in livestock breeding and production with no emphasis on increase in the final product has been reversed. Today there are 55,800 veterinary medicine stations at all levels in the country, and breeding farms, livestock improvement stations, breeding stations, and frozen semen stations total 2,600. Including grassland work stations and such livestock veterinary medicine enterprises and unit units, the country has 580,000 veterinary medicine personnel.

Prospects for Development of the Livestock Industry

Deputy Minister Cai continued talking to the correspondent about the questions of the need for continued development of China's livestock industry and how it would develop.

He said. He said that even though very good accomplishments had been made in development of the livestock industry during the past 3 years; nevertheless, it was still a very far way from being able to satisfy the daily increasing needs of the material lives of the people. At the present time, the standard of living of China's people rests mostly on grain and vegetables supplemented by meat and eggs. In 1980, national average per capita consumption of meat was only 24.5 jin, and of eggs between 5 and 6 jin. This standard is still very low. If the people of the country are to live a "comfortable life" by the end of this century, continued vigorous development of the livestock industry will be necessary.

Today the gradual improvement in the livelihood of urban people has steadily placed new demands on livestock products. On the one hand there is increased demand for lean pork and for beef, and lamb as well as for fresh milk and poultry eggs. On the other hand, the need for industrial goods used in daily life made from hides and hair also has become increasingly great. In addition, the number of draft animals used in agriculture and female livestock animals of proper age also require further development.

Cai Ziwei said that the livestock, industry in China requires great development, and conditions exist for great development as well. In China there is 3.3 billion mu of grasslands that can be used, 1 billion mu of grassy mountains and grassy slopes, several hundred million mu of grasslands in forests, and 200 million mu of ocean beaches, which are precious resources for development of the livestock industry. Most of the large quantities of stalks and stems, husks, and cake residues from farm crops, and more than 100 million mu of green manure crops make good fodder for livestock. Formerly use of these resources was sometimes inequitable, sometimes insufficient, and sometimes not at all.

About 30 percent of the workforce in the farflung rural villages of China is surplus. Following institution of various economic policies in rural villages and the implementation of systems of responsibility for production, a large amount of the workforce is being converted to economic diversification. The adaptation of general methods to local situations for the development of hog raising, cattle raising, sheep and goat raising, poultry raising, rabbit raising, and beekeeping can soak up a large amount of the workforce. Once these raising industries have developed, local processing can also soak up large quantities of the workforce. Abundant workforce resources is yet another advantage in China's development of a livestock industry.

Deputy Minister Cai said that the program set for development of the livestock industry at this national agricultural work conference was as follows: Guided by the principle of comprehensive development of farming, forestry, and livestock, pastoral areas are to be used chiefly for livestock, emphasis going to development of economic diversification in livestock industry production. Farming areas should combine farming, forestry, and livestock, with all around development of a livestock industry and the adaptation of general methods to local situations to make the most of advantages, and lay stress on key points. Suburbs of large and medium size cities should mostly produce milk, poultry, eggs, and meat. The conference adopted some concrete policies and actions to be taken for development of the livestock industry including the following:

Active development of household livestock raising industries, support being given for capital, fodder, and superior breeds.

Further implementation of systems of responsibility for production, with proper handling of production and marketing relationships, and continued operation of pilot projects for integrated livestock, industrial, and commercial enterprises.

Continued restructuring of livestock industration administration systems.

Increased production of fodder grass and feeds

Vigorous advocacy of scientific livestock raising. Training of more livestock, veterinary medicine, and grasslands scientists and technicians.

WELL BEING OF RURAL VILLAGES PORTRAYED

Hong Kong CHING-CHI TAO-PAO [ECONOMIC REPORTER] in Chinese No 6, 15 Feb 82 p 19

[Article by Yang Qingwen [2799 1987 2429]: "Brief Summary of Agricultural Production and Peasants' Livelihood"]

[Text] Despite the continuous occurrence of severe floods and droughts in some provinces and autonomous areas of China in 1981, the estimated total output value of agriculture for the country as a whole still showed an increase of about four percent over the previous year. Total output of grain is estimated to have increased by about 30 billion jin over the previous year, close to that of the bumper harvest year of 1979. On the heels of an all-time high record in 1980, a new breakthrough in cotton was made in 1981. After 3 consecutive years of increases in output of oil-bearing crops, continued increase occurred again in 1981. It may be said that all around increase in output of 12 different crops including grain, cotton, edible oil, hemp, silk, tea, sugar, vegetables, tobacco, fruit, medicinal materials, and miscellaneous crops occurred. Meat, eggs and fruit also registered varying degrees of increase. This was a change from the past when increases in output of grain meant reductions in economic crops and contraction of economic diversification.

Accompanying all around increases in output from agriculture and a raise in purchase prices paid for farm products has been another obvious increase in peasant income in 1981 on top of fairly great increases during the 2 previous years. As of the end of November, rural savings deposits this year were up 29 percent over the same period last year. Rural savings per capita nationwide amounted to somewhat more than 23 yuan, somewhat more than five yuan more than at the end of the previous year. In Guangdong Province peasant savings have steadily increased year by year. In 1978 commune members' saving amounted to almost 670 billion yuan, and in 1981 this leaped to almost 2.2 billion yuan, a more than threefold increase in a three year period. In the relatively poverty stricken rural villages of Guizhou Province, in 1981 peasant average per capita income for the province increased somewhat more than eight yuan over the previous year.

In the course of the last 4 years, rural villages in China have built 1.5 billion square meters of houses, meaning an average increase of almost 2 square meters per capita for the 800 million peasants in the country. In rural Jiangsu, almost one-half the peasant households built new houses. In Yanan Prefecture in northern Shaanxi, in the course of 1980 45,800 cave dwellings were built, more than the number built during the past 10 years. Last year another group of new houses was built. Statistics show that 150 million rural households in the country would like to build new houses.

Very great increases has taken place in rural needs for the means of production and the means of livelihood. When the peasants have money, they first develop production, then build new houses, and then marry a wife,and buy a trousseau. Rural requirements for consumer goods have also risen. In addition to the "three great items" (bicycles, sewing machines and wristwatches), they want high and medium quality clothes, television sets, large clocks, and fine furniture.

In rural villages today, discussion groups on scientific farming have exerted considerable attraction on the peasants, particularly on rural youth. Some communes are operating classes in crop cultivation, scientific fertilization, and bredding of varieties which young peasants from all over come forward to participate in. The masses say, "Now that responsibility for fields has been set, everyone is trying to become a technician." Wherever a cadre walks, a large group of people follows." Fuyang Prefecture in Anhui set up 53 technical information sites which received more than 20,000 inquires between March and September last year.

BRIEFS

FRESHWATER FISH BREEDING INCREASES--Beijing, 10 Mar (XINHUA)--China's 1981 fresh-water fish catch was 1.37 million tons, 29.8 percent more than 1978, according to a national fresh-water fishing conference that opened here today. Pond, lake reservoir and river surface area used for fish breeding is three million hectares, 10 percent more than 1978, said Xiao Peng, director of the State Administration of Aquatic Products. [Beijing XINHUA in English 1224 GMT 10 Mar 82]

PRAWN CATCH EXCEEDS QUOTA--Beijing, 5 Mar (XINHUA)--China's prawn catch in 1981 exceeded the state quota by 11.5 percent, even though some breeding centers were hit by typhoons. Prawns now are bred in 90 coastal counties and cities, compared with only a dozen in 1978. China's prawn industry has expanded with the adoption of artificial breeding methods for prawn larvae. In recent years, a series of measures have been taken to expand prawn breeding. A National Prawn Breeding Company, established in 1979, manages prawn breeding, processing, sales and import and export business. China now has 300 technicians and 500 skilled workers involved in the breeding of prawns. Training courses for the workers also have been conducted in recent years. [Text] [Beijing XINHUA in English 0812 GMT 5 Mar 82]

VEGETABLE COOPERATION GROUPS ESTABLISHED--Xian, 9 Mar (XINHUA)--Three high-yield vegetable cooperation groups have been set up here by agricultural departments and scientific research institutes in 17 cities. The groups exchange production and technical information in an effort to boost vegetable production in big and medium-sized cities. The cities include Beijing, Tianjin, Shanghai, Shenyang, Harbin, Nanjing, Wuhan, Chengdu, Xian, and Lanzhou. Cooperation started in Beijing in 1980 when agricultural departments and scientific research institutes in the capital city organized a group. Using modern vegetable production techniques under the group's guidance, the city's 1,300 hectares of tomatoes averaged 43.5 tons per hectare in 1980, 13.5 tons more than in the previous year, the Ministry of Agriculture said. Per hectare yield reached 45 tons in 1981. An inter-city cooperation group, involving Beijing, Tianjin, Shenyang, Xian, Taiyuan and Jinan, was formed in early 1981 on the advice of the ministry. Experiments on high-yield tomatoes and cabbages were made in the suburbs of these cities. [Text] [Beijing XINHUA in English 1219 GMT 9 Mar 82]

SUXIAN PREFECTURE REAPS OVERALL BUMPER HARVEST IN 1981

Beining GUANGMING RIBAO in Chinese 11 Jan 82 p 1

[Article by Dong Buxiang [5516 2975 3276] and Shao Changfu [6730 7022 1381]: "Managing the Popularization and Application of Agricultural Science and Technology Like Managing the Production Responsibilitiy System, Anhui's Suxian Prefecture Realizes Overall Bumper Harvests in Agriculture Last Year"]

[Text] Anhui province's Suxian Prefecture is located in the plain north of the Huai River and has suffered from many disasters for a long period. Its agricultural yields are low. But comparison of 1981 and the previous year showed the yield of food grains increased 24.2 percent. The yield of oil bearing crops increased 24.5 percent, and the total agricultural income increased 34.13 percent. Per capita income of farmers was 260 yuan, an increase of 69 yuan from the previous year. Recently, the prefecture committee summarized the situation in agricultural production and believed that implementation of the production responsibility system has stimulated the farmers of the whole prefecture to actively learn science and use science, and it has improved the standard of scientific planting. This is an important reason for the realization of bumper harvests in agriculture.

In recent years, the Suxian prefecture committee strengthened leadership in scientific planting. A deputy secretary took charge of this work, and he frequently conducted studies, planned, inspected, summarized, helped the agricultural department solve some of the practical problems in the popularization of agricultural techniques. The prefecture committee and the administrative office relied on agriculture technicians and cadres and drew up the "plan for the popularization of agricultural techniques in 1981-1985 for the whole prefecture". At the same time, agricultural specialists and technical personnel were organized as the prefecture's agricultural techniques advisory group to serve as a scientific and technical counseling agency to lead production, to participate in decision making, and to solve major technical problems in agricultural production. The main leading members of the prefecture committee and the administrative office led in learning science and using science, frequently listened to agricultural techniques classes, and joined technicians on trips to villages to investigate, study and solve problems.

The Suxian prefecture committee has exerted much effort in popularizing agricultural production techniques that require less invettment, that produce many benefits, that produce quick results, and that are easy to implement.

It has popularized in a key way the application of such techniques as the cultivation of superior varieties of agricultural crops, improvement of low yielding soils, comprehensive prevention and control of harmful cotton insects, machine sowing of wheat, sidedressing for the roots, deep application of chemical fertilizers, and plowing green manure under, dense planting of peanuts and irrigation of farmland by spraying and artificial insemination of large domesticated livestock. Attention was also paid to popularizing new techniques in diversification such as cultivation of pearls in river clams, raising martens, and raising silkworms.

Suxian Prefecture also used training classes, field meetings, night schools, broadcasts of lectures, technical counseling, signing technical contracts and many such forms to popularize agricultural science and techniques. According to statistics, the whole prefecture has held over 2,000 technical training classes. It has held training over 50,000 times for technical backbone members. It has held over 2,000 scientific and technical seminars with an audience of over 250,000 and it has printed over 1 million copies of scientific and technical data.

'BAN YUE TAN' DISCUSSES ECONOMIC CONTRACTS

HK101230 Beijing BAN YUE TAN in Chinese No 4, 25 Feb 82 pp 21-22

[Article by Gong Xianggeng [7895 7449 1649] and Wu Zheng [2976 2398]: "Production Teams Should Pay Close Attention to the Signing of Economic Contracts"]

[Text] At present, of the production teams that have introduced various versions of the contract responsibility system in our Fuzhou area, some have followed the pattern of concluding economic contracts, setting out the economic relationship between the production team and the peasant household, or between the operation group and trained personnel and their respective rights and obligations. This has played a very helpful role in developing production and arousing mass enthusiasm. But due to a heavy workload and the pressure of production tasks, many production teams have still not had time to conclude formal economic contracts with commune members who have actually committed themselves. Even where a contract has been signed, unstable factors still exist. This has, to different degrees, affected the morale of the masses and interfered with the development of production. Therefore, we should act without delay in upholding the spirit of the No 75 document of the CCP Central Committee and the Central Rural Work Conference and handle well the business of concluding contracts in a realistic manner.

On the basis of the production responsibility system, we must extensively introduce an economic contract system. This is an important measure in using economic means to cope with production and distribution within the framework of the collective economy. The contracts for production and for task completion concluded by the production team with groups, households and workers clearly specify the economic responsibilities assumed by the parties concerned. Such contracts can serve not only as plans guiding production but also as rules to be followed in correct handling the "three relationships." Where production teams are committed to contracts for task completion on a household basis, this can take the place of the previous year-end distribution programs. Therefore, we must fully arouse the masses to hold democratic consultations, so that economic contracts can be based on a mass foundation and on policy, become economic instruments which have a binding effect on both sides and also have the teeth of law.

In light of the actual conditions of our prefecture, economic contracts generally cover the following:

1) Under the guidance of state plans, production teams arranging to commit households to farming plans for staple crops and production quotas as the basis of production and task completion contracts;

2) Assigning the means of production, such as land, mountain forests, water surfaces, farm cattle, farm machines and implements, production facilities, etc, to commune members;

3) Assigning purchase quotas and special quotas for grain, cotton, oil-bearing crops, pigs, fish, poultry, eggs and other agricultural and sideline products to be sold by commune members to the state;

4) Deducting that which should be contributed by commune members to the production team's collective public funds which include public reserves, public welfare funds, subsidies for "five-guarantee" households and family members of militarymen and martyrs, family planning costs, expenditures on people-run primary schools and other necessary welfare funds;

5) Obligating commune members, where public welfare undertakings, voluntary work and so forth are concerned.

Economic contracts that are concluded after democratic consultations and signed by both parties must be observed and their fulfillment must be guaranteed. If one party purposely acts in contravention of a contract, the other has the right to hold the former responsible financially and even legally. If the production team tears a contract to pieces, its relevant responsible personnel should be held responsible. If a commune member who is bound by a contract breaks it, the production team, apart from exercising its right to reclaim land, mountain forests, water surfaces and other means of production assigned to him, can subject him to necessary financial punishment in order to ensure the fulfillment of an economic contract.

BEIJING RADIO COMMENTS ON AFFORESTATION DRIVE

OW090112 Beijing Domestic Service in Mandarin 1200 GMT 6 Mar 82

[Station commentary: "Strive For Results in Afforestation"]

[Text] The yearly arbor day is approaching. The national voluntary tree-planting campaign is gradually developing. In the upsurge of afforestation to cover the motherland with trees, we must strive for results, be responsible for the planting and survival of those trees planted and make sure that trees will grow into useful timber.

Since liberation, we have planted trees year after year and the areas afforested have added up to 1.3 billion mu. However, only 420 million mu of these areas have actually grown into forests, and some of the trees are of poor quality and of no value as timber. A great deal of manpower, material and financial resources and time have been wasted.

This year is the first year of the national voluntary tree-planting campaign. We must conscientiously sum up past experience and lessons, make a good start and strive for solid, good results. First, we must firmly establish the idea of quality first as our guiding thought and must not practice formalism.

Afforestation is a task of fundamental importance involving hundreds of millions of people. It must be well-planned and carried out in a well-prepared and organized way and with leadership. Everyone taking part in afforestation must earnestly fulfill his responsibility and make sure that every tree planted survives.

Next, it is necessary to practice scientific afforestation. Ours is a vast country with varying climatic conditions. It is necessary to select suitable tree stocks depending on local soil, weather, topographical and geomorphical conditions and other actual conditions.

Many people think there is not much to learn about planting trees. That is a misconception. Different trees have different living habits and characteristics and require very different natural conditions. We should follow the principle of planting trees according to local conditions and must not act rashly.

To achieve the expected results in afforestation, the key lies in effectively implementing forestry policies. It is necessary to ensure the "three fix's"--to fix mountain forest rights, rights to wastelands and the forestry production responsibility system--so the masses will not only have the enthusiasm in afforestation but will have a sense of responsibility for forest management. Only when policies are correct and remain stable for a long time will the masses' enthusiasm for afforestation be sustained. Only in this way will it be hopeful for trees to grow into useful timber.

Afforestation and covering the motherland with trees is an important strategic task and a great undertaking to benefit future generations. To change the lack of forested areas in our country and basically improve our country's ecological environment will require the hard work of several generations of people. A journey of 1,000 li begins with the first step. If we start now, work in a down-to-earth way and make solid progress, the great goal of covering the motherland with trees will assuredly be accomplished.

BEIJING VEGETABLE SUPPLY SITUATION REPORTEDLY IMPROVED

Beijing BEIJING RIBAO in Chinese 1 Jan 82 p 1

[Article by Wu Maodong [0702 2021 2767]: "Suburban Beijing Vegetable Farmers Last Year Sold 2.1 Billion Jin of Vegetables to the State. Vegetable Area Communes and Brigades Strictly Observe Policy of 'State Monopoly Purchase and Exclusive Selling Rights,' and Strictly Fulfil Contracts Signed with Commercial Units, Strive to Deliver to Market in Accordance With Quotas and Plans, Enthusiastically Serve the City, and Assure Vegetable Supplies in the Capital's Markets. Supplies Still Not So Good in Some Areas, With Not Much Seasonal Varieties in Some. Broad Masses of Vegetable Farmers Resolve to Further Upgrade Vegetable Output Levels to Make New Contributions in Providing Vegetables"]

[Text] The correspondent has learned from the authorities concerned that in 1981 suburban vegetable farmer sales of vegetables to the state totaled 2.1 billion jin. This is a manifestation of vegetable farmer love of country, having the cardinal principles in mind and taking the overall situation into account, concern for the overall situation, and caring about work style. They have enthusiastically served the city, and have made a contribution in assuring a vegetable supply to the markets of the capital city.

In 1981, Beijing was more than 90 percent self-sufficient in vegetables. These vegetables plus those brought in from elsewhere meant the daily marketing of close to 6 million jin for a daily per capita consumption averaging more than 1 jin for the residents of the city and towns of the municipal area.

Last year the vegetable growing areas of the municipality further instituted a program of "taking vegetables as most important," and "service to the city." While generally establishing various forms of a system of responsibility for production, all communes and brigades vigorously launched scientific farming. They gradually enlarged the growing area in preserves, actively promoted advanced farming techniques and superior varieties, and equitably adjusted crop sequencing. Taken together with favorable climatic conditions, this made for pretty good vegetable harvests and no lowering of output. This showed up rather noticeably during the slack season. Because of circumstances in the Beijing area, during the three months of April, August, and September in every former year, market supplies of vegetables have been fairly short, and in some years there has even been a dirth of them. Last year saw improvements in vegetable supplies during the slack season. In the 2 months of August and September alone, the vegetable growing areas provided the capital's market with more than 410 million jin of commodity vegetables for a situation better than in previous years. At the end of last December, the Municipal CCP Committee and Municipal Government held a conference in which 212 production teams received commendations and awards for their achievements in providing supplies during the slack season of August and September.

Under the guidance of the state plan, all communes and brigades in vegetable growing areas have striven in every way possible in accordance with market demand to produce varieties that sell. Things like persimmons, big chili peppers, and melons, fruits, and pulses rather favored by the people of the city have increased by more than 30 million jin over previous years for further changes in the composition of available varieties. During the months of June and July alone, more than 140 million jin of persimmons reached market, an increase of more than 30 million jin over the same period in previous years for a second all-time high, and for an initial change in the short supply situations of the past few years.

In order to assure market supply, each of the communes and brigades in the municipal vegetable growing area last year instituted a policy of "state monopoly purchase and exclusive selling rights," and strict fulfillment of contracts signed with commercial units to make market deliveries in accordance with quotas and plans. Numerous communes and brigades sold vegetables to the state whenever they had any, determinedly refusing to divide and sell them privately. During a very recent period, some unscrupulous dealers intent on speculation and profiteering scurried around the close-in suburbs offering high prices to vegetable growing teams for their vegetables. But cadres and commune members told them: We sell our vegetables to the state; we won't sell them to you at any price!

In summary, supply of vegetables was not bad last year, but was still not too good in some places, and some seasonal varieties were not very plentiful. Most recently the municiaplity put forward a policy of unswerving implementation of "taking vegetables as most important," to place vegetable production in a premier position. Vegetable production must be regulated mostly by plans; there can be no growing of whatever one likes. Vegetable fields must be cherished and neither permitted to be rented out nor used just as one likes. Scientific research should be strengthened to upgrade vegetable output. The broad masses of vegetable farmers have further upgraded vegetable output levels in accordance with municipal demand to make a new contribution in supplying vegetables during 1982 and succeeding years.

INCREASES IN AVERAGE PER CAPITA COLLECTIVE INCOME DISTRIBUTIONS REPORTED

Income Up in 41 Counties

Fuzhou FUJIAN RIBAO in Chinese 16 Dec 81 p 1

[Text] Statistics from the province's rural work committee, which was convened a few days ago, show that in 41 of the province's counties and municipalities this year, rural village per capita income (the collective distribution portion) amounted to more than 100 yuan. This means a doubling over last year in almost two-thirds of the province's counties and municipalities.

In eight of these counties and municipalities the average per capita collective portion of income was more than 150 yuan. They were Sanming City, Changtai, Jianyang, Shaowu, Changle, Longhai, Zhaoan, and Jianning. Places in which per capita income averaged between 100 and 150 yuan included Nanping, Shunchang, Pucheng, Jianou, Songqi, Chongan, Guangze, Zhenghe, Ninghua, Mingqi, Yongan, Qingliu, Shaxian, Jiangle, Taining, Longqi, Minqing, Yongtai, Fuqing, Shanyou, Xiafu, suburban Xiamen, Xinglin, Tongan, Zhangzhou City, Nanjing, Zhangfu, Dongshan, Yunxiao, Huaan, suburban Fuzhou, and Huangcheng. Sanming City, which has been a front runner in the collective portion of average per capita income, this year took first position in the province again with an increase from 154 yuan to 175 yuan.

As a result of the implementation of various forms of a system of responsibility for production, arousal of the enthusiasm of the masses, adaptation of general methods to local situations to make the most of advantages, readjustment of agricultural crop patterns, and development of economic diversification, this year these communes and municipalities, in which the collective portion of average per capita income amounted to more than 100 yuan, won general all around increases in production and earnings in agriculture. In the 10 counties and municipalities of Jianyang Prefecture where the collective portion of average per capita income has been rather high for many years, per capita income averaging 136 yuan, every county averaged more than 100 yuan per capita, and in Guangze and Pucheng counties, per capita income increased 20 and 35 yuan respectively. In Zhangfu, Xiafu, and Yongtai counties, where average per capita income has been below the average for the province, an all around bumper harvest was obtained in this disaster year in both grain and economic diversification. Both grain and money were abundant, and the collective portion of average per capita income was more than 100 yuan, for increases of 30 and 40 yuan respectively, making them the counties with the greatest increase in income in the province. In Nanjing County, which this year sustained particularly heavy flood damage, though grain output suffered from the disaster, thanks to efforts in economic diversification the collective portion of average per capita income also increased from last year's 100 yuan to 114 yuan.

Increases in More Than 200 Brigades

Fuzhou FUJIAN RIBAO in Chinese 16 Dec 81 p 1

[Article by Zheng Yizheng [6774 5030 2973]]

[Text] Rural production brigades in the province with average per capita incomes (collective distribution portion) of more than 300 yuan rose in number from 53 last year to 224 this year, for a 3.2 fold increase.

This year's standout crop of production brigades were commonly characterized in the following ways: All were rather ideologically emancipated. They were able to conscientiously carry out party policies in rural villages and adept in administration and management leadership teams. They were able to build various forms of a system of responsibility for production in accordance with the desires of the majority of the masses. They were skilled in making the most of local manpower and resources for development of economic diversification and brigade run enterprises. The Yanling Production Brigade of Mantanghong Commune in Quanzhou City organically combined farming, forestry, livestock raising and sideline occupations, each of them promoting the other. As a result, the collective portion of average per capita income this year increased from last year's 280 yuan to 370 yuan, vaulting it into the ranks of the standout brigades. Yangfang Production Brigade in Chengguan Commune, Sha County is an advanced brigade that has developed farming, industry, and sideline occupations in an all around way. Last year its collective portion of average per capita income reached 310 yuan. Though early grain crop output this year declined as the result of calamity, thanks to the firm attention given economic crops and brigade run enterprises, income increased. In addition to the 600,000 yuan in public accumulation funds retained, an average of somewhat more than 324 yuan per capita remains for distribution to commune members.

Some production brigades sensibly readjusted the structure of their agriculture this year to make the most of local advantages, the economic benefits derived being more remarkable. Yaoxia Production Brigade in Guzhu Commune, Yongding County is suited to the growing of flue-cured tobacco. This year they had self determination, and the entire brigade made major plantings of flue-cured tobacco. Average per capita earnings from this crop alone amounted to 224 yuan. Caiban Production Brigade in Jiuhu Commune, Longhai County made the most of its advantages for the growing of narcissus flowers, expanding their planting to 140 mu. From this crop alone, increased per capita earnings amounted to 212 yuan, and the collective portion of average per capita income for the entire brigade this year may reach 530 yuan. Kengyuan Production Brigade in Shuangyang Commune, Zhangping County energetically developed production of dry bamboo shoots, and this year average per capita collective income may be more than 500 yuan. Some fishery production brigades along the seacoast implemented systems of responsibility after which both the catching and the hatching of aquatic products developed. Liansheng Production Brigade, in Guantou Commune, Lianjiang County and Haiqiong Production Brigade in Jingfeng Commune, Huian County had average per capita collective incomes of more than 1,200 yuan. The masses praised the system of responsibility for bringing prosperity to the brigade and plenty to the people.

SHAOWU COUNTY COMMODITY GRAIN SETS RECORD

Ruzhou FUJIAN RIBAO in Chinese 11 Dec 81 p 1

[Article by Fang Yurui [2455 3768 3842], County Reporting Office; Li Shengyuan [2621 516B 3293] and Wu Peigen [0702 1014 2704], County Farm Office: "Shaowu Peasants Correctly Handle Relationships Among the Three. [State, Collective, and Individuals] Sales of Grain by Somewhat More than 1,600 Households Exceed 10,000 Jin, Average Per Capita Grain Sales Being 820 Jin to Exceed the All-time High"]

[Text] Shaowu County, northern Fujian Province's major commodity grain production area, reaped a bumper grain harvest this year after which the broad masses of commune members eagerly sold excess grain to the state. There were more than 1,600 households in the county that sold 10,000 jin of grain, commune members in five such households selling more than 20,000 jin. Commodity grain supplied the state from the county averaged more than 820 jin per capita to exceed the all-time high.

In Shaowu County, more than 70 percent of all production teams practiced a system of responsibility this year of either contracting production to individual teams or to individual workers, which aroused the enthusiasm for production of the broad masses of commune members resulting in a bumper agricultural harvest. Grain output for the county increased by more than 11 million jin over last year, and average per capita output of grain was 1,647 jin. Following the bumper grain harvest, the broad masses of peasants praised the party's policies and did not forget to support building of the four modernations, eagerly selling grain to the state. According to incomplete statistics, peasant households in the county who asked to sell more than 10,000 jin of grain numbered somewhat more than 1,690 a 1.5 increase over last year. Among them were five households of commune members who sold more than 20,000 jin. Xiedang Production Brigade in Dazhu Commune, and Gushan Production Brigade in Yanshan Commune, both of which had fairly tremendous increases in output, had more than 230 commune member households each of which asked to sell more than 10,000 jin of grain. Commune members in five households, including those of Chen Qingrong [7115 3237 2837] and Liu Wenzhong [0491 2429 1813] sold 60,550 jin of grain to the state from the first crop, and received a commendation from the commune. In Datian Production Team with 11 commune member households, seven households realized plans for households to sell 10,000 jin of grain. Commune member Zheng Zuowu [6774 0155 2976] sold the state 10,607 jin of grain from the first crop and another 9,500 jin from the late crop. Commune member Huang Youliang [7806 2589 5328] of Shuqian Production Team, Hushu Production Brigade undertook responsibility with the production team for the farming of 32 mu from which he harvested more than 15,000 jin of grain in excess of quota, and sold the state more than 20,000 jin of excess grain. Numerous peasant households not only sold much grain but sold good grain. Wangbanjie Production Team commune member Wu Peirong [0702 1014 2837] hired a vehicle and sent to the grain station for sale to the state more 10,600 jin of first quality well filled out paddy after he had dried and winnowed it. Somewhat more than 300 jin of paddy that had deteriorated as a result of having been soaked with rain, he kept for consumption.

Eagerness to sell grain on the part of the broad masses of peasants has given impetus to the work of grain units. In this county, grain units have set up an additional 10 grain purchasing sites and have sent 26 persons into rural areas to work with grassroots levels in grain procurement work. As of 6 December, the county had fulfilled 96.7 percent of its grain procurement quota. Because storage capacity cannot keep pace, some of the grain from the 10,000 jin of grain commune members has not yet gone into storage.

PUTIAN PREFECTURE BOOSTS WHEAT GROWING

Fuzhou FUJIAN RIBAO in Chinese 7 Dec 81 p 3

[Article by Fang Zhunhua [2455 2182 5478], Putian Prefecture Liaison Station: "Putian Prefecture Has Planted 340,000 Mu of Wheat, Barley and Naked Barley. Adapts General Methods to Local Situation in Large Planting of Wheat"]

[Text] Putian Prefecture has made the most of its good natural resources and abundant workforce resources to do a conscientious job of winter planting. The prefecture has already planted 341,000 mu of wheat and barley for completion of 60 percent of planting plans.

This year Putian Prefecture got a head start on winter planting. During the autumn harvest, the Prefecture CCP Committee and government administrative offices convened meetings to make specific assignments of winter planting tasks. They called upon all counties and communes to conscientiously honor the self-determination of production teams, to adapt general methods to local situations in laying out winter planting plans, to do everything possible to grow more when more can be grown, and to take in hand winter planting, treating it as a major crop. Putian County began winter planting in mid-October, and now 70 percent of the wheat and barley area has been planted. Yongtai County organized a professional winter planting crops personally led by principal leaders who went into the fields to give specific guidance and help solve actual problems. The area to be planted to wheat and barley in the prefecture this year is 560,000 mu, 80,000 more mu than last year.

Additionally the prefecture has also planted more than 200,000 mu to rape, broad beans, and Chinese milk vetch.

MORE SCIENTIFIC FARMING, GREATER AGRICULTURAL DIVERSIFICATION URGED

Fuzhou FUJIAN RIBAO in Chinese 30 Nov 81 p 1

[Article: "Next Year's Emphasis in Agriculture on Science and Technology and on Economic Diversification Is Proposal by Comrade Xiang Nan [7309 0589] at Provincial Finance and Trade Work Conference"]

[Excerpts] The secretary of the Standing Committee of the Fujian Provincial CCP Committee, Xiang Nan, said at the Provincial Finance and Trade Work Conference that the situation in agriculture in Fujian Province this year is very good. The guiding principle for the province's agricultural production next year should be the practice of two stabilities and two transformations. By this is meant the stabilization and perfection of systems of responsibility for production in agriculture as a foundation for shifting the work emphasis to science and technology; and while assuring steady increases in grain output to shift the work emphasis to economic diversification, including to forestry, animal husbandry, fisheries, and commune and brigade enterprises.

Xiang Nan noted that in the practice of a program of two stabilities and two transformations, in the field of science and technology Fujian Province would have to take in hand seeds and breeding, and come to grips with equitable use of fertilizer and water to upgrade standards in scientific farming to make the most of the power of agricultural science and technology. In the fields of forestry, animal husbandry, fisheries, and commune and brigade enterprises, the most should be made of Fujian's advantages in having many mountains and broad seas.

Wen Xiushan [3306 4423 1472], [member of the Standing Committee of the Provincial CCP Committee and director of the Provincial Agricultural Commission], said that the Provincial CCP Committee had recently made a study of the entire economic situation in Fujian Province and had proposed that the entire economy of Fujian, beginning in 1982 and after 3 or 4 years of efforts, should take off in 1985. By beginning is meant the year in which the rate of increase in total output value of agricultural production remains steady at around seven percent. By takeoff is meant the year in which the annual rate of increase attains double digits, i.e., above 10 percent. For all economic work, construction of eight bases is to be given serious attention in 1982, with a reading of a "testament to the mountains and the seas." Construction of four bases for forestry, animal husbandry, the fishing industry and economic crops is to be taken in hand. Launching of a socialist patriotic education campaign centering on "four upholds," "three multiple considerations," and "two oppositions" is to be done in an effort to fulfill an increase in total output value of agriculture of 300 million yuan, a 300 million jin increase in grain output, a 30 yuan increase in average earnings of commune members (including income from both the collective and from household sideline occupations), and control of the net natural rate of increase at 10.5 per 1,000.

Speaking to issues in the system of responsibility for agricultural production, Wen Xiushan said that we should continue to put into effect pertinent directives from the Central Committee, adhere to the principles of adaptation of general methods to local situations, tailored guidance, and permitting economic diversification without change. This is to say adherence to the collective road in agriculture for a long time without change, public ownership of the basic means of production (mostly land) for a long time without change, building of systems of responsibility for agricultural production in accordance with requirements of the collective economy for a long time without change, and permitting diversity in the forms of a system of responsibility for a long time without change.

PROVINCIAL REQUIREMENTS ON SUGARCANE SET

Fuzhou FUJIAN RIBAO in Chinese 7 Dec 81 p 1

[Article by Provincial Sugar Refining Industry Company: "Proposal That Attention Be Given Several Problems During New Crushing Season Made at Cane Sugar Production Conference Convened by Provincial Government"]

[Text] The sugar mills in Fujian Province began crushing sugarcane in early December. The provincial government convened a cane sugar production conference at which it took up the new situations and new problems that had appeared in cane sugar production following institution of a system of responsibility for agriculture. It put forward several problems that should be focused on for solution during the new crushing season so as to assure fulfillment of production quotas for 420,000 tons of sugar during the 1981-1982 crushing season.

This year the province will harvest 706,000 mu of sugarcane, a 58,000 mu increase over the last crushing season. It is estimated that this area will supply more than 3.5 million tons of sugarcane for crushing. Sugar mill production capacity has also been further increased. Not only have 31 large and small sugar mills increased their crushing capabilities by more than 2,000 tons through tapping potential, making improvements, and restructuring, but four newly built 500 ton sugar mills have formally gone into production, and one 2,000 ton enlarged sugar mill has begun experimental production. Sugar production capacity in the province has increased by 60.8 percent over the last previous crushing season, an increase that is virtually commensurate with increase in sugarcane. In order to make full use of Fujian Province's advantages in producing cane sugar, comrades in charge from all the main sugar producing prefectures, municipalities and counties who attended this conference, all the principal departments involved, and leaders of the large and medium size sugar mills conscientiously discussed new problems that have occurred in cane sugar production since the institution of systems of responsibility for agricultural production, and made several requests about production in the new crushing season as follows:

1. Further strengthening of leadership engaged in cane sugar production. All major producing prefectures, municipalities, and counties are to be the specific responsibility of a deputy prefect, deputy mayor, or deputy county head. All units concerned in all prefects are to closely coordinate, divide responsibility for labor, and discover and solve problems in a timely fashion.

2. The work of cutting, hauling, purchasing, and looking after sugarcane is to be done conscientiously. Sugar mills are to buttress planning in their work and, on the principle of cutting the cane that ripens first, work out plans in common with communes and brigades for cutting and hauling, as well as sign economic contracts. Communes and brigades are to sell sugarcane to the state on time, of proper quality, and in proper quantity. Hauling of sugarcane will be done mostly by communes and brigades, sugar mills and hauling units playing an ancillary role in hauling, and the hauling potential of the people being used to the full. Hauling personnel are to submit themselves to regulation to do the hauling in accordance with plans. "Backdoor deals," and extortion are to be strictly punished.

3. Implementation of policies to win the confidence of the people. The grain, fertilizer, sugar, or money to be paid for procurement of sugarcane will be figured up by sugar mills and the authorities concerned for settlement with production teams. Production teams are to make settlement with commune members on the basis of the system of responsibility of fixing output quotas on a household basis, so that commune member income from increased output of sugarcane will be greater.

4. Strengthening of sugarcane management to improve economic benefits. Raw sugarcane is not to be permitted to enter market trade, and theft or looting of sugarcane is to be severely punished. No small sugar mills are to be set up in cane growing areas. That portion of sugarcane that large sugar mills are "unable to digest" may be crushed by small sugar mills, provided the Provincial Planning Commission approves. However, sugar output must be taxed according to regulations and procured by the state. Any sugar mills set up without authorization shall be outlawed.

5. Sugar mills are to improve administration and management and all around quality controls for further improvement in output and quality of sugar, improving the utilization rate per 10,000 tons of sugarcane by improving quality, lowering waste, and reducing costs.

BRIEFS

TOTAL GRAIN OUTPUT--Fujian Province achieved an all-round bumper harvest in 1981 with total grain output surpassing a record high of 16 billion jin. The total output of longan, oranges and tangerines, flue-cured tobacco, tea, rapeseed and peanuts also reached a record high. [Excerpt] [Beijing BAN YUE TAN in Chinese No 3, 1982 p 10]

JINJIANG COUNTY LAND SALES--In 1981 grain output of Jinjiang County, Fujian, dropped by more than 10 million jin because large tracts of cultivated land had been used for building houses. In the townships of Qingyang, Shishi and Anhai, some people have even sold the plots, which are contracted to them for farming purpose, at the cost of 1,300 yuan per 0.1 mu. [OW161041 Fuzhou FUJIAN RIBAO in Chinese 4 Mar 82 p 2 OW]

JIANYANG PREFECTURE GRAIN OUTPUT--In 1981 Fujian's Jianyang Prefecture turned out 2.586 billion jin of grain, topping 1980 by 136 million jin, and procured more than 910 million jin of grain, topping 1980 by 121 million jin. [Fuzhou FUJIAN RIBAO in Chinese 4 Mar 82 p 2 OW]

FOCAL POINTS FOR AGRICULTURAL SCIENCE, TECHNOLOGY GIVEN

Shijiazhuang HEBEI RIBAO in Chinese 7 Dec 81 p 2

[Article by Li Feng [2621 6912], Deputy Provincial Governor Hebei Province: "Let Systems of Responsibility for Agricultural Production and Scientific and Technological Work Proceed in Tandem"]

[Excerpts] The urgency and importance of current attention to agricultural science and technology work must be further recognized. Since the Third Plenary Session of the 11th Party Central Committee, accompanying readjustment of the national economy has been an increasing recognition on the part of leadership cadres at all levels, and of the broad masses of the people, of the important position of science and technology work in development of the national economy. Accompanying implementation and perfection of various forms of a system of economic responsibility in the farflung rural villages has been emergence of the study of science, love of science, and use of science in a "craze for science and technology." In some places supply cannot keep up with demand for popular reading materials on agricultural science, in a situation of "difficulties in buying books." As a result of institution of systems of responsibility for production, linkage to production is like linkage to one's heart, and only through applied science and technology can yields be increased for increased earnings. Investigation by units concerned shows that peasants who have systematically mastered agricultural science and technology number only about 30 percent of the total. Forty percent of the peasants act as though they understand without really understanding, and another 30 percent, particularly a large number of youths between 20 and 30 years of age, have no grasp of farm work techniques. In the past they relied on their brawn to earn workpoints, but with the advent of contracting of production, they feel urgent need to study technology. Not only do peasants need to study technology, but rural cadres also urgently need to study technology, because blind guidance will not work, and executive orders won't have any effect either. The Central Committee has further clarified programs for scientific and technical development, suggesting that science and technology must be combined with economics and society, and that science and technology must serve the national economy to solve the problem of orientation of scientific and technological work. We need to diligently solve the problem of all levels of leadership not understanding, or not relying upon science, or shouting empty phrases, combining scientific and technological work with systems of responsibility so that they work in tandem to effect great changes in agricultural production.

Science and technology has to be converted directly into productivity as quickly as possible. Next year, we will take in hand the following seven scientific and technical tasks.

1. Continuation of agricultural resource surveys and agricultural zoning work. This is a basic task for the formulation of policies that relies on science.

2. Diligent action to develop research and spread the results of science and technology. Major projects in development of research are new varieties and new strains of wheat and demonstration experiments in use of water and fertilizer; new strains of cotton and superior varieties of cotton, and demonstration experiments in use of water, fertilizer, and prevention and control of diseases and insect pests; new strains and new varieties of millet, and demonstration experiments in scientific use of water and fertilizer; new strains and superior varieties of corn and demonstration experiments in scientific use of water, fertilizer, and prevention and control of diseases and insect pests; demonstration experiments on bumper crop techniques for potatoes; demonstration experiments using new strains and superior varieties of oil-bearing crops (such as peanuts, flax, and sunflowers); demonstration experiments on introduction of superior varieties ofpasture grasses and on use of green manure to improve soil; demonstration experiments on balanced increases in yields of fruit trees and on early fruiting culturing techniques for young orchards; demonstration experiments on new varieties and new techniques in the growing of melons; and demonstration experiments on maintenance of purity in breeding of rabbits, and research on lean meat hogs. In addition, the Provincial Bureau of Agriculture also proposed an equitable crop pattern for wheat varieties; culturing techniques for cotton varieties Lumian No 1, Jimian No 2 (Zhengchang No 1), Jimian No 3) (disease resistant variety); culturing of Qingdaolao summer millet; culturing techniques for strengthening wheat seedlings before the onset of winter; companion cropping of summer corn to preserve a full stand of stalks; disease resistant spring millet and lodging resistant summer millet; resistance to drought in mountain and hill regions to permit spring sowing for a full stand of plants; intercropping of grain and pulses; full stands of sturdy cotton seedlings that develop early; culturing techniques using plastic sheeting to cover the ground; increasing fertilizer for and increasing the number of clumps of peanuts transplanted plus reducing the number of buds [so those remaining grow larger], and giving early care; application of results of soil surveys; growing of green manure to nurture soil fertility; comprehensive prevention and control of cotton bollworms; and use of hybrid dominance in vegetables, providing such scientific and technical projects for promotion to all places for their consideration. Other individual bureaus under jurisdiction of the province also put forward their own projects to be emphasized for promotion, and gave much attention to their implementation. In addition, on the basis of their own situation in adapting general methods to local situations, all prefectures and counties made arrangements for promotion of their own projects.

3. A good job in the building of modern agricultural bases, with the launching at Luancheng and Nanpi of agricultural modernization experiments to explore the way.

4. Intensification of seed work. Concentration of forces to do a good job of experimental demonstration work with superior varieties of seeds and seeds that show promise of being superior varieties that are suited to growing in Hebei Province. Intensification of experimental research work on varieties that tolerate drought, tolerate alkalinity and tolerate poor soil, and improvement in organization and coordination in order to change as quickly as possible the backward condition of Hebei Province's seed work.

5. Taking in hand development for use of the Tahang mountain region, starting with high yields of fresh fruits, and the raising of small domestic poultry and small livestock animals to make use of the resources in the 24 counties of the Taihang mountain region.

6. Use and improvement of the Heilonggang region. This entails promotion, on the one hand, of the experiences of the Zhangzhuang Brigade in Quzhou County, and of Wuma Battalion in Nanpi County in clearing up alkalinity, and making the most of advantages of local farming traditions on the other, adapting general methods to local situations, using strengths and avoiding weaknesses to make full use of the soil resources of Heilonggang region.

7. Solution to technical problems in development of economic diversification, organizing scientific research, production, and marketing into a continuous process. In the raising of hogs, chickens, rabbits, and martens, superior varieties should be introduced and scientifically raised, epidemic diseases prevented and controlled.

Strengthening and Reorganizing of Agricultural Research and of Promotional Organizations. Institutes above the prefectural level engaged in research on farming, forestry, irrigation, meteorology, and fisheries should be strengthened, and a good job done with the several institutes of the Academy of Agricultural Sciences. Major current problems should be focused on and major research projects in farming, forestry, animal husbandry, sideline occupations, and fisheries should be drawn up on the basis of conditions in the province, and efforts coordinated to serve agricultural production. In doing research, in addition to research on individual projects, importance should be given macrocosmic, comprehensive research. Agricultural research units are to abide by major decisions on agricultural problems. Promotional organizations below the county level require improvement. All counties should set up promotion stations with subordinate specialized teams. Every commune should arrange to have one qualified technician, who is excused from production work, whose responsibility it is to give attention to promotion work. In addition an organization of peasant technicians, both those partially excused from production work and those not excused from production work, should be formed. When technical positions are being evaluated, promotion personnel are not to write slanted articles, but are to look at technical accomplishments, technical standards, and professional capabilities of personnel. Those having conspicuous accomplishments are to be given rewards. Commune farms, superior variety farms, and production brigades and production team demonstration farms are to continue operation.

A Good Job of the Popularization of Science. Commune science popularization societies and production brigade science popularization propaganda stations are to be set up and perfected. Rural agricultural technicians, veterinary personnel, teachers as well as those possessing specialized skills, and the broad masses of cadres who support science popularization work should be organized.

FOUR COUNTRIES ACHIEVE BUMPER HARVESTS DESPITE DISASTERS

Qing County Scores Successes

Shijiazhuang HEBEI RIBAO in Chinese 8 Dec 81 p 1

[Text] Qing County has actively promoted various forms of a system of responsibility linking compensation to output, has adapted general methods to local situations in readjustment of crop patterns, had developed economic diversification and commune and brigade enterprises, and has triumphed over serious drought and wind disasters for all around increases in output and earnings from farming, forestry, animal husbandry, sideline occupations, and fisheries.

This year, despite a 700,000 mu reduction in its grainfield area, the county's grain output increased over last year, output totaling 180 million jin. The county contributed 21 million jin to the state, an 87.3 percent increase over last year. It also realized "10 breakthroughs" as follows: First was in total autumn grain output, output this year being seven percent greater than the all-time high year since founding of the People's Republic. Second was output value from economic diversification, which increased 14.5 percent over the all-time highest level. Third was output value from commune and brigade enterprises. Forecasts call for achievement of 76.56 million yuan, a 440,000 yuan increase over the all-time high level. Fourth was commodity output of agricultural byproducts, which was 18 percent higher than the all-time high level for the same period. Fifth was a total output value of agriculture this year amounting to 94.7 million yuan, a 12.6 percent increase over the all-time high. Sixth was average per capita distribution of earnings, which was 110 yuan, a 16.5 percent increase over the all-time high. Seventh was total amount of commune member savings, which amounted to 8,474,000 yuan between January and October, a 22.5 percent increase over the all-time high for the same period. Eighth was total retail sales of goods, which amounted to 52.45 million yuan for the period January to October, an 11 percent increase over the all-time high for the same period. Ninth was the building of more than 30,000 new houses by commune members, a 23 percent increase over the all-time high. Tenth was that as of the end of October large livestock animals in inventory in the county numbered 29,207 head, an increase of 4,197 head over the all-time high for the same period for an increase of 16.7 percent.

Today in the farflung rural villages of Qing County, the peasants have money and they have grain; an increasing number have bought furniture, added new equipment, taken wives, or built new houses. In the cities and countryside of the county the economy is flourishing and markets are brisk, presenting a delightful picture of happy people in a fat year.

Lincheng County's Sesame, Pulse Production

Shijiazhuang HEBEI RIBAO in Chinese 8 Dec 81 p 1

[Text] This year Lincheng County contracted out to commune members, who submitted bids, its poor hill lands that lay uncultivated, and land in out of the way places for the growing of sesame and pulse crops, deriving tremendous increases in yields therefrom. Total output of sesame in the county may reach 1.4 million jin, and total output of pulses may reach more than 3 million jin, these outputs being close to the totals for the past 10 years in each case. Sales to the state of 650,000 jin of sesame have been made. This is 35 percent more than the total sold the state during the past 10 years. Pulse sales amounted to more than 440,000 jin, more than double the total amount sold to the state during the past 10 years. Throughout the county a large number of households that harvested more than 1,000 jin of sesame and pulses has appeared.

Ding County Grain Output Records

Shijiazhuang HEBEI RIBAO in Chinese 8 Dec 81 p 1

[Text] Despite serious calamities this year as a result of drought, wind, diseases, and insect pests, Ding County's grain yields per unit of area amounted to 685 jin, a 52 jin increase over last year. Total output was 587 million jin, an increase over last year of 39 million jin. Both were all-time highs.

In order to do a good job of agricultural production this year, all communes and brigades in Ding County took firmly in hand the perfection and upgrading of systems of responsibility for agricultural production. Now 94.7 percent of production teams in the county have instituted various forms of a system of responsibility for production, which has aroused the eagerness for production of the broad masses of cadres and people. On this basis, they have also given attention to scientific farming. Leadership cadres, technicians and technical mainstays throughout the county who have received various kinds of training total more than 370,000. In addition, systems of personal responsibility for technicians have been established to arouse their enthusiasm to give guidance to peasants in farming to assure bumper harvests in agriculture.

Bumper Production in Weichang

Shijiazhuang HEBEI RIBAO in Chinese 8 Dec 81 p 1

[Text] Weichang County's practical action in developing livestock production and promoting systems of responsibility in which compensation is linked to output has aroused the enthusiasm of the peasants. This year the county's grain output may reach 226 million jin, a 43 million jin or 22 percent increase over last year. The livestock industry created all-time high records. Large livestock animals number 120,700 head, an increase over last year of 6,700 head for a six percent increase. Sheep and goats number 386,000 head, an increase over last year of 57,300 head for a 21.1 percent increase. Throughout the county 22,059 slaughter sheep have been purchased by the state this year for a 91.8 percent overfulfillment of quotas.

HENGSHUI PREFECTURE SUCCESSES IN LINKING EARNINGS TO OUTPUT HAILED

Per Capita Income Increase in Gucheng

Shijiazhuang HEBEI RIBAO in Chinese 5 Dec 81 p 1

[Text] The 1,124 people in 297 households in the six production teams of Wuhu Production Brigade, Gucheng County farm 2,664 mu of land. Prior to the Third Plenary Session [of the 11th Party Central Committee], this production brigade was known throughout the country as "poor in three ways." Its grain yields were just a little more than 300 jin per mu; its cotton yields were just a little more than 30 jin per mu; and per capita income averaged just a little more than 110 yuan. This year, after instituting a system of responsibility of specialized contracting, calculation of compensation being linked to output, despite severe drought, grain yields reached 1,474 jin per mu; cotton yields reached 190 jin per mu, and per capita income averaged 957 yuan. In one leap it became the advanced unit in the prefecture.

How can such a great change take place within such a short period of time in a poor and backward village? The key lies in the CCP Committee and the Management Committee of this brigade having diligently acted in the spirit of the Third and Sixth Plenary Sessions [of the 11th Party Central Committee] to integrate realities with leftist criticism and criticism of the leftist errors of the principle persons in charge of the former Provincial CCP Committee, to emancipate mentality, and to act in terms of realities in the brigade to put into effect a system of responsibility of specialized contracting whereby compensation was calculated in terms of output. At the same time, they readjusted the internal structure of agriculture to expand the cotton growing area, and vigorously developed both economic diversification and commune member household sideline occupations. Acting on the basis of the activities in which the entire village was engaged and the skills of its workforce, as well as on the desires of its people, they set up individual specialized farming teams, specialized cotton growing teams, specialized sideline occupation teams, specialized machine maintenance teams, and specialized forestry teams. They also instituted a work contract system of responsibility for grain grinding mills, shops selling on commission, and medical treatment stations, signing individual contracts with each of them, which were reconciled at year's end. In the case of cotton production contracted by commune members, an output of 80 jin per mu was paid, with a bonus of 0.70 for every jin in excess of this quota, all amounts greater than

than 120 jin per mu going entirely to the growers. In the case of sideline occupation teams with 95 people in them, annual earnings were set at 16,000 yuan. Once this quota was reached, each person had 10 workpoints recorded daily. At year's end, 50 percent of earnings in excess of quota and up to 20,000 yuan were retained as bonuses for sideline occupation personnel. Earnings of more than 20,000 yuan were entirely distributed as bonuses to sideline occupation personnel. In the case of shops selling on commission and medical treatment stations, fixed numbers of employees and fixed annual earnings were set, the employees bearing sole responsibility for all profits and losses.

After Wuhu Production Brigade instituted a system of responsibility of specialized contracting, calculation of compensation being linked to output, full advantage was taken of workforce and material resources. All around bumper crops of grain, cotton, and oil-bearing crops were harvested in a year of severe drought; accumulations were further increased; and reproduction expanded.

Zaoqiang County's Greater Output, Earnings

Shijiazhuang HEBEI RIBAO in Chinese 5 Dec 81 p 1

[Text] Puzhuang Production Brigade in Tanglin Commune, Zaoqiang Country has six production teams consisting of 313 households. This is a notoriously poor village where, in most years, labor is valued at 0.10 to 0.20 yuan, or sometimes as little as 0.07 to 0.08 yuan. No bonuses have been paid here in 12 years. The village has 60 bachelors over the age of 25, and annually 60 members of its workforce leave the village for elsewhere, so 1,500 mu of its cultivated land has been left uncultivated. This year, following institution of a system of responsibility, the enthusiasm for production of commune members reached unprecedented heights. Total output of autumn grain alone increased 2.4 fold over total output for all of last year; total output of cotton increased 5.1 fold over last year; and per capita earnings increased by an average 6.8 fold over last year.

This brigade had implemented a work contracting system of "three unifieds" and "five fixeds." The "three unifieds" were unified planting plans, unified watering of land, unified eradication of insect pests. The "five fixeds" were fixed plots of land, care and use of fixed farm animals and farm tools, fixed subsidy payments to cadres and people not engaged in production, fixed care [of the indigent] and fixed withholdings. In order that this system of responsibility would be steadily improved upon, the brigade CCP branch and management committee made sure to constantly study new situations and promptly solve new problems. They took practical action to eradicate commune member apprehensions. At first commune members feared the system of responsibility might change, so they dared not put an investment into the fields for which they were responsible. Party branch secretary Li Jun'ge [2621 0193 2706] thereupon took the lead in making an investment, fertilizing the fields for which he was responsible with 160 jin of urea and 50 jin of ammonium carbonate to spur commune members on. In three production teams, plots that had been contracted out were scattered, making it inconvenient for commune members to farm them. Brigade cadres helped these three teams readjust these plots, changing the system from contracting for the total amount of fields to contracting for individual parcels. After contracting work had been done, a large amount of surplus workforce remained. In order to find opportunities for this surplus workforce, 500 mu of land that had been left uncultivated were contracted to commune members for farming, the cotton growing area being expanded by 200 mu, and the oil-bearing crop area by 300 mu. Help was also given commune members in development of economic diversification, the brigade seeking opportunities, issuing certifications, and handling procedures. This year 65 households are firing bricks and tiles; three households are keeping bees; six households are doing carpentry work; four households are operating turpentine making shops; five households are operating beancurd making shops, five households are making vermicelli; three households are processing rice noodles, and three households are working rubber. In addition, two specialized construction teams with a total of 30 people, have been set up. In this way 127 households in the brigade, a workforce of 180 (amounting to 42 percent of the total workforce) has been put to work at economic diversification or household sideline occupations, and an unprecedently flourishing scene has taken place in agricultural sideline occupations. Though farm animals and farm tools much increased following contracting of work responsibility, both were insufficient to the needs of commune members' farming. In order to solve this problem, brigade cadres went around to each household to make a full registration. They organized each household for mutual cooperation, and they organized use of machines for farming so that every household will be able to plant wheat on time this fall.

High Grain Output in Hengshui County

Shijiazhuang HEBEI RIBAO in Chinese 5 Dec 81 p 1

[Text] Xili Production Brigade in Heyan Commune, Hengshui County has two production teams consisting of 63 households. This year they have instituted unified management with a system of responsibility whereby fixed output quotas are assigned individual able-bodied workers, winning extraordinary economic results, and the appearance of a large number of "outstanding households" with high outputs, high contributions to the state, and high earnings. The 12 households in the production brigade with annual outputs of 10,000 jin each account for 20 percent of all households in the village, five of them having produced 10,000 jin of grain from the fall season crop alone. Twenty households sold more than 5,000 jin of surplus grain to the state in the fall (the brigade tendered the summer crop). These 20 households accounted for 31.7 percent of the total number of households in the village. The 23 households with distributions from the collective averaging an annual more than 300 yuan per capita amount to 37 percent of the total number of households in the village.

In its practice of unified administration with a system of responsibility whereby fixed output quotas were assigned individual able-bodied workers, this brigade formulated collective adherence to six unifieds, namely unified planting plans, unified machine farming, unified watering, unified investment, unified assignment of workforces, and unified distributions. It practiced "three contracts and one reward," namely contracting for labor, contracting for output, and contracting investment, with commune members getting full rewards and being responsible for all losses incurred. This system was guaranteed not to change for a period of 3 years. Once this form of a system of responsibility was set, commune member eagerness for production immediately zoomed. After care of wheat began this spring, the brigade was supposed to invest a certain amount to buy chemical fertilizer for commune members, but the brigade was out of maney at the time. So 38 commune member families took the initiative in advancing the brigade money, which was used to buy 8,600 jin of chemical fertilizer. The brigade planned to repair 2,300 meters of field ditches to stop them from leaking, and commune members went right to work. Now 1,300 meters have already been prepared. The production brigade CCP branch focused on new problems that had arisen following implementation of the system of responsibility, and buttressed ideological and political work. For five commune members whose tending of the fields for which they were responsible was good, citations of merit were promptly issued, commune members throughout the village were called upon to emulate them, and their experiences were spread throughout the production brigade. For hardship households comprised of the old, the weak, the orphaned, the widowed, and those that had lost their able-bodied members, the brigade arranged to send special people to grind flour and provide such farm work as their strength would permit to make sure that their livelihood would be no lower than the median. In addition, following practice of the system of responsibility, some households took the initiative to link up, exchange labor and help each other, the brigade lending support and encouragement so that mutual assistance became the order of the day throughout the village. In this way, this brigade's unified administration with a system of responsibility whereby fixed output quotas were assigned individual able-bodied workers brought huge forces into play, and output of grain and oil-bearing crops exceeded the all-time highs.

AGRICULTURAL READJUSTMENT, MECHANIZATION, RESULTANT LABOR SURPLUS DISCUSSED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 12, 5 Dec 81 pp 15-16

[Article by Luo Jingbo [5012 0513 2672], Research Office, CCP Central Committee Secretariat: "A Look at Readjustment of the Agriculture Structure in Terms of Heilongjiang"]

[Excerpts] Results Remarkable From Readjustment of Structure of Agriculture

Heilongjiang's main farming areas are located on the alluvial plains of the Sunghua and Nen rivers, and on the marshy plain at the confluence of the three rivers [possibly the Mutan Jiang, the Tangwang He, and the Tongken He]. This area is large, the soil fertile, water abundant, and hours of sunshine long. They constitute the greatest naturally richly endowed commodity grain bases. However, during those years under a program of "taking grain as the key link," when only the production of grain was deemed important and when even the world renowned and nationally highly favored "northeast soybeans" were forced out because of their "low yields," and when attention was given only to "high yield crops" such as corn soybeans had to be companion cropped with corn, having no choice but to "seek survival in any crack." This situation did not permit grain output in Heilongjiang to achieve the development it should have achieved. It was not until 1977 that grain output for the province amounted to somewhat more than 22 billion jin. Commodity grain provided that year amounted to only somewhat more than 6 billion jin.

Following the Third Plenary Session of the 11th Party Central Committee, the Heilongjiang Provincial CCP Committee acted in a practical way to diligently implement the Central Committee's program of giving attention to planting in accordance with local conditions, and the development of economic diversification. First of all, it designated grain and bean growing zones and miscellaneous grain growing zones according to natural conditions and traditional farming practices, and implemented scientific regionalization in farming. For example, it designated the Nenjiang administrative region, with its short frost-free period, a production zone for wheat and beans, and designated the Suihua administrative region's numerous counties as zones for growing of paddy rice, to convert sandy land to the growing of peanuts, and to continue the growing of corn on high downlands. The masses liked this, which made easy the preservation of millet, the sown area of which has also greatly increased during the past 2 years. As a result of readjustment of the crop structure, despite serious natural calamities, Heilongjiang's grain output in 1979 and 1980 equaled that of the bumper year of 1978, amounting to more than 29 billion jin. Commodity grain output also rose from 9.6 billion jin in 1978 to 11 billion jin in 1980. This year, except for a serious decline in output of state farms in the east as a result of serious flooding, a good harvest is expected.

Concurrent with readjustment of the internal structure of grain crops has been appropriate expansion in Heilongjiang in recent years of the growing area of sugarbeets, flax, sunflowers, and flue-cured tobacco, which have been fairly rapidly increased to more than 10 million mu, an increase from a 4.7 percent ratio of total area sown in 1977 to 7.9 percent. This year the area sown to economic crops has been further expanded, increasing by 15.6 percent as compared with 1980.

The Provincial CCP Committee has also further liberalized policies for some impoverished counties and communes to encourage them to proper further development of some economic crops.

Mutual Advancement of Agricultural Mechanization and Economic Diversification

The lessons of the past have been summarized for concentrated investment, during the past 2 or 3 years, in mechanization and complete equipping of Heilong's agriculture. Mechanization as been done first in prosperous areas and in areas where results can be quickly obtained, thus using a set of methods that stress practical results and economic benefits. For example, during the past 3 years, the state has provided 14 million yuan in loans for agricultural mechanization to Keshan County, 8 million yuan of which can be recovered as early as this year. Loans given in any given year can be entirely recovered following the autumn harvest in the same year.

Following agricultural mechanization, usually a very large surplus of workforces results. For example, in the rural villages of Keshan County, 85 percent of the work force formerly was engaged in farm work; today it is only 50 percent. In some miscellaneous grain growing areas, in particular, where the average number of people required to farm the land is somewhat less, the proportion of surplus workforce is even greater. What is to be done with this resultant surplus workforce? This has been a very great consideration in the promotion of agricultural mechanization. Today, however, a way out has been found under guidance of a program for development of economic diversification. First is putting together all kinds of specialized teams for the accumulation of manure, breeding, vegetables, fruits, and field water conservancy, to do intensive farming, and to make advances in depth and in breadth in agricultural production. Second is development of forestry, animal husbandry, sideline occupations, and fisheries to broaden avenues of production. Third is development of commune member family sideline occupations, making use of private plots, land for the growing of animal fodder, and land for the growing of fuel crops, and developing family growing and family hatching industries. Fourth is operation of commune and production brigade industries. Fifth is development of contruction material and construction industries for the building of new farm villages and small cities and towns. Sixth is operation of restaurants, hotels, photographic, tailoring, and repair facilities.

Agricultural mechanization and economic diversification advance each other and complement each other. Prior to mechanization, numerous communes and brigades relied on economic diversification to increase income and accumulate funds for mechanization. Following mechanization, they again depended on economic diversification to provide opportunities for surplus workforces. Development of mechanization has smashed the narrow outlook of handicraft labor, permitting a division of labor and a division of trades for production, and also giving impetus to development of specialization in economic diversification.

The all around development of agricultural production has raised numerous new requirements in all quarters that await solution:

1. Increased attention to making the most of the power of science and technology.

2. Urgent need for enhancement of processing of agricultural byproducts, their transportation and sale.

3. Full use of Heilongjiang's role as the largest commodity grain base in the country. In order to promote national economic development and gradually reduce grain imports, Heilongjiang has to be able to gradually supply the country more commodity grain, particularly to provide the nutrient-rich soybeans that the people of the entire country need. In order to solve this problem, contradictions existing between the central government and localities, and between the state and the people, on grain problems have to be better solved to further arouse their enthusiasm for production of grain and beans.

BUMPER HARVEST DESPITE 100 DAYS DROUGHT REPORTED

Wuhan HUBEI RIBAO in Chinese 5 Dec 81 p 1

[Article by Wang Xinchao [3769 2450 2600] and Han Chaoxiong [7281 2600 7160]: "State Support Wins Bumper Harvests, and Bumper Harvest Do Not Forget Support to State. Despite 100 Days of Severe Drought This Year, Jingmen County Harvests 1.1 Billion Jin of Grain. Bumper Crop Peasant Households Tender State 440 Million Jin of Grain For Overfulfillment of Requisition Purchase Quotas"]

[Text] Peasants in Jingmen County, who won bumper harvests through reliance on state support to triumph over serious drought, have eagerly sold their surplus grain to the state. The country has already sold 440 million jin of grain to the state for overfulfillment of its requisition procurement grain quotas for the year.

Jingmen Country grows 1.2 million mu of paddy rice, making it one of the province's principal commodity grain bases. Between April and August this year, the county had not one soaking rain and suffered a serious 100 day drought. Thanks to arousal of the enthusiasm of the masses as a result of the system of responsibility that linked compensation to output, the irrigation benefits derived from state constructed water conservancy projects, and the vigorous support rendered by industry, and by finance and trade units, the drought was overcome and a bumper harvest won, the county's grain output totaling 1.1 billion jin. According to statistics, this year the county put to work in combat against drought more than 6,200 pieces of power machinery with more than 150,000 horsepower. All of the more than 10 large and small electrically powered irrigation stations on Huangdang Lake and Chang Lake, which had been built with capital invested by the state, were used, consuming more than 24 million kilowatt hours of electricity. During the height of combat against drought, Zhanghe Reservoir daily pumped more than 40 cubic meters of water per second, providing more than 300 million cubic meters of water to assure a bumper harvest for the irrigation zone's major rice producing communes of Yandun, Tuanlin, Wuli, Shili, Shiqiao, and Zengji. Industrial, and finance and trade units promptly provided rural villages with large amounts of chemical fertilizer, pesticides and diesel fuel. Agricultural scientific and technical units organized more than 8,000 technicians to go down to the grassroots to provide guidance to peasants in scientific farming. The peasants said. With this year's severe drought, but for the party's good policies, the country's timely support, and Zhanghe Reservoir's assured irrigation, a great disaster could have taken place. Now it is rice resulting from policies that we are eating, and socialist prosperity that we are enjoying.

Following the bumper grain harvest, everyone eagerly sold their excess grain to the state. Peasants from Wuli Commune in the Zhanghe irrigation zone, remembering the source of their prosperity, sold to the state 5.5 million jin of grain over and above fulfillment of their requisition procurement quotas. Every one of the 181 production brigades that last year received government assistance when stricken with an especially severe flooding and waterlogging disaster, this year harvested a bumper crop. One hundred sixty of these production brigades sold to the state a total of 140 million jin of surplus grain. As of mid-November, the number of households in the county that had sold the state from 10,000 to 30,000 jin of grain numbered 8,030.

DEGRADATION OF LOCAL ECOLOGY BLAMED FOR FARMING PROBLEMS

Huanggang HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 11, Nov 81 p 16-18

[Article by Wang Zhongqin [3769 0022 2953], Huanggang Prefecture Science Commission: "Discussion of Farmland Construction Problems in Huanggang Prefecture"]

[Excerpt] Huanggang Prefecture has 7,377,000 people and only 6,961,000 mu of cultivated land, the average amount of cultivated land per capita being less than two-thirds the national average. With such a small amount of farmland, if agriculture is to improve further work in building farmlands is clearly particularly important. We have won remarkable achievements in the building of farmland and water conservancy since Liberation; however, in terms of total needs, our building of farmlands is not yet over the hump. As of 1980, effectively irrigated farmland area in the prefecture totaled 5,777,000 mu, or 83 percent of the total area. The area from which harvests could be taken despite waterlogging or drought totaled 4,096,000 mu or 58.8 percent of the total area. The area producing consistently high yields was 2,584,000 mu or 37.1 percent of the total. This is to say that under normal circumstances, one-sixth of the farmland would be difficult to irrigate; in years of normal harvests, most fields would not produce high yields; and in years of slight disaster, almost one-half of farmlands would be threatened with drought or waterlogging. In 1979 total grain output broke 6 billion jin (not including Echeng, the same applying elsewhere in this article). This represented a twofold increase over 1949. However, in the course of 30 years, consecutive yearly increases occurred only in the three year period from 1955 to 1957, while consecutive yearly decreases were limited to the 4 year period 1966 to 1969. Cotton output fluctuated for 8 years following 1965 creating a total output record only in 1974, while yields per unit of area fluctuated for 13 years, a breakthrough taking place only in 1979. Reasons for inconsistent yields are numerous, but in terms of the internal agricultural situation, one of the major reasons was that the building of farmlands was not up to snuff.

First of all the soil presented many obstacles to high crop yields. Take Xishui County where a second soil survey has been completed. The country has 12 percent of wetlands and 48.5 percent of drylands, an overly large amount of them having sandy soil. About 30 percent are cold, waterlogged, muddy fields, low-lying lake or river fields, and intermediate blue mud fields. Soil nutrients are imbalanced, and the soil is seriously deficient in phosphate and potash, 72 percent of cultivated land lacking phosphate, and 46 percent lacking potash. Soils are slightly acidic, those with a pH of less than 5.5 accounting for 38.5 percent of the total. If the situation in Xishui County, which has a fairly good basis for agricultural production, is like this, the situation in other counties may be imagined.

The natural ecological system in which the farmlands are located have also been seriously damaged. Data from authorities concerned show that, at the time of the general survey in 1975, land in the prefecture used for forestry had decreased by 3.36 million mu since the period immediately following Liberation, a decline of 23.1 percent. Despite a forested area of 8,653,000 mu, timber reserves averaged only 1.2 cubic meters per mu or only one fourth the national average. Furthermore, the three manys in the composition of forests, namely many young and mid-age forests (accounting for 97.1 percent), many coniferous forests (pine and fir accounting for 94.9 percent), many natural forests (accounting for 59.5 percent), and the three fews in the structure of forests, namely few branches, few grassroots level forests, and few areas with a vegetation cover, greatly reduced the role of forests. Take the quantity of erosion in forests. Data from inside China and from abroad indicate that soil erosion generally averages about 2 tons per square kilometer of forest, but measurements taken by the Shiqiaopu water and soil conservation station in the prefecture show forest soil erosion to be more than 78 tons. In 1980 the eroded area of the prefecture amounted to 8,256.7 square kilometers or 38.6 percent of the prefecture's total area, and 2,466.2 square kilometers of this total or 30 percent of the area needing control, has yet to be brought under control. Calculations based on the soil erosion modulous for various kinds of topography as measured by the Shiqiaopu water and soil conservation station, show that from the more than 2 million mu of barren mountains, cultivated slopes and low standard terraced fields, annual erosion amounts to 4,234,000 tons of soil. The serious soil erosion causes many riverbeds to rise by an average more than 3 centimeters annually, and silt entering reservoirs throughout the prefecture averages 6,341,000 cubic meters annually, which amounts to the scrapping of one medium size reservoir every year. As a result of the reclamation of lakelands to create fields, by 1980 lake water surfaces for the entire region amounted to only 500,800 mu or only 41.4 percent the area immediately following Liberation. As a result the agricultural climate has tended to deteriorate. Analysis of 30 consecutive years of meteorological data by the Wuhan and Huanggang meteorology stations shows an average decline in precipitation of 179.5 millimeters during the 1960's as compared with the 1950's, and a decline of 94.2 millimeters in the 1950's as compared with the 1960's. The longest consecutive number of days without rain in a year averaged an increase of somewhat more than 2 days per decade. The longest consecutive number of days of rainfall and amount of rainfall, in a situation of decreased rainfall, increased slightly in the 1970's as compared with the 1950's. This shows a tendency toward concentration of periods of precipitation during a decline in volume of rainfall, which can easily result in drought or waterlogging disasters.

SHAANXI REALIZES SELF-SUFFICIENCY IN EDIBLE OIL IN 1981

Beijing GUANGMING RIBAO in Chinese 11 Jan 82 p 1

[Article: "Rely On Scientific Planting to Change the Situation of Consuming Reissued Edible Oil for 14 Years, Shaanxi Province Realized Self Sufficiency With Surplus of Edible Oil Last Year"]

[Text] Report by reporter Liu Binggi [0491 3521 3823]: Shaanxi Province which has consumed reissued edible oil provided by the state for 14 years has realized self sufficiency in edible oil in 1981. In 1980, the total yield of oil bearing crops throughout the province has reached 219.4 million jin, creating the highest record in history. The amount produced in 1981 registered an increase of 50 percent over 1980, breaking the 300 million jin mark.

A very important reason for Shaanxi Province's rapid development of its production of oil bearing crops was the popularization of advanced techniques in a big way and the implementation of scientific planting besides the party's policies which mobilized the enthusiasm of the commune members and besides the readjustment of crop distribution by suiting measures to local circumstances. During the past 2 years, the agricultural departments at each level and the scientific research units in agriculture in Shaanxi Province have done a lot of work to improve rape varieties. They have cultivated and popularized "Zao feng No 2", 'Zao feng No 3", "Shaan you 110", "S7211" and such a series of superior varieties which suit this province's natural characteristics. Visible results have been achieved. The concerned agricultural, scientific and techncial departments of the province have also organized scientific and technical personnel of scientific research units in agriculture at the three levels of the province, prefecture and county to conduct experiments at certain localities, and they have separately developed techniques of cultivation of rape for different regions, such as the Hanzhong Basin, Gunzhong paddy fields and dry plateaus of the region north of the Wei River. Over 1,800 specialized personnel and over 100,000 farmer technicians were trained. They have popularized advanced techniques on a large scale, and they have more thoroughly changed the situation of rough cultivation and tehhnical backwardness in the cultivation and production of rape.

JINZHONG PREFECTURE POPULARIZES AGROTECHNIQUES TO DEVELOP PRODUCTION

Taiyuan SHANXI RIBAO in Chinese 18 Dec 81 p 1

[Article by Pan Yaodong [3382 2565 2639] and Liang Ruojie [2733 5387 3381]: "Popularize Techniques Among All Families, Rely on Science to Increase Yield, Increase Income and Become Rich, the Jinzhong Prefecture Popularizes the Application of Agricultural Science and Techniques With Visible Results"]

[Text] As the year 1982 is about to arrive, welcomed news is heard from the Jinzhong Prefecture in the popularization of the application of agricultural science and techniques with visible results: In 1981, the science committee of the administrative office selected and implemented 36 agricultural science techniques, and because they suited the natural conditions of the locality, and because concrete measures were well matched, most served a visible function in promoting production, increasing income and creating wealth. They have enabled scientific techniques to develop great power in agricultural production.

In recent years, 22 scientific research achievements in agriculture developed by the Jinzhong Prefecture received national and provincial awards. To enable these advanced techniques to be popularly utilized and to become practical productive forces, the prefecture committee and the administrative office established a "new techniques popularization leading group" in September of last year, and the committee also established a plan to popularize and apply new techniques aimed mainly at "less investment, quick results, large gain". These techniques mostly suit the locality's natural characteristics. The soil is infertile. Drought easily occurs. The frostless period is short. Spring is cold and the temperatures are low. The 69 brigades in the six cotton planting counties in the prefecture used thin sheets to cover over 1,140 mu of cotton fields, and each mu produced an increase of 59.3 jin over the cotton fields cultivated by ordinary methods. The science committee of Taigu County launched the method of "letting scientific techniques go ahead and go to the villages". Thus, commune members of 522 families planting watermelons also learned to use sheets to cover the ground and increased income by over 420,000 yuan. The 20,000 mu of millet in Jiexiu County increased their yield by over 30 percent because of the popular use of the "jinzhuang method of cultivating high yields of millet" despite the drought that occurred in spring and summer this year. Yuci and Heshun counties expanded the area of test planting of summer wheat. After harvest, the per mu yield of winter wheat averaged an increase of 135 percent. The "xia mai No 1" popularized over 268 mu in the hilly regions of Yuci County yielded nearly twice as much as the other varieties planted in similar soil.

While popularizing the application of new agricultural techniques, the scientifics, the scientific techniques department at each level in Jinzhong Prefecture also paid a lot of attention to sicentific guidance in diversification. Gaocun Brigade in Qi County used frozen semen to improve the yellow buffalo. In one year's time, it increased income by 21,900 yuan, a per capita average of 42.10 yuan. Bodi Brigade of Pingding County built fish ponds with a water surface area of over 200 mu and utilized surplus heat from the nearby power plant to cultivate fish scientifically. Now, it has propagated over 80,000 African crucian carp. In addition, the agricultural science deparments at the three levels of the prefecture, the county and the commune also popularized knowledge about the techniques of raising silkworms, deer, and martens scientifically in many ways among the broad number of commune members through training in special subjects, by teaching them in villages and by broadcasting lectures. They have opened new roads for the farmers to become rich quickly.

ZHEJIANG

WIDER USE OF GRAINS OTHER THAN WHEAT, RICE URGED

Hangzhou ZHEJIANG RIBAO in Chinese 22 Dec 81 p 1

[Article: "Need for Use of Superior Varieties and Superior Methods in Developing Minor Edible Grains. Delegates and Experts Attending Provincial Minor Grains Evaluation Conference Suggest All Jurisdictions Give Serious Attention to Minor Grain Output"]

[Text] Great prospects exist for development of minor grains [grains other than wheat and rice] in Zhejiang Province, the crux lying in use of superior varieties and superior methods. This was the unanimous view of delegates and experts attending the Provincial Minor Grains Evaluation Conference convened by the Provincial Seed Company and recently held in Shangyu County.

Avenues are broad for Zhejiang Province's development of minor grains. It is possible to expand the growing of these grains to places such as seacoasts and yellow soil hills where major grain crops cannot be grown, and they can occupy a major position in open fields to play the role they should play in readjustment of the farming system. In regions in which output from a wheat -rice - rice system of farming is not high, the system may be changed to wheat - beans - rice, or wheat -rice-beans, or else a single rice crop system can be changed to a two crop system of beans and rice. In addition, minor grain crops may be intercropped or companion cropped for three dimensional farming. Otherwise odd corners of fields or small scraps of unused land may be used to grow them, sticking them in wherever possible. There are many varieties of grain crops that may be grown; they have a wide range of uses; labor costs are small; economic value is high; and they are a good method for combining nuture and use of soil as well as a good avenue for increasing output and earnings. Today less than half the area of the 1950's is devoted to the growing of minor grain crops. Everyone acknowledges that this state of affairs must be changed with all possible speed, and that cadres and commune members must come to understand the importance of developing minor grains if avenues are to be opened so that minor grains can get a foothold. Last year Wenzhou Prefecture companion cropped 70,000 mu of soybeans, 20,000 mu of mung beans, and more than 1,000 mu of seasame on its sweet potato lands alone for increased harvests of more than 7 million jin of soybeans, more than 1.2 million jin of mung beans, and more than 10,000 jin or sesame.

The experts agreed that it is necessary for the development of minor grain crops to direct attention both to numerous varieties and to high yields.

Today output of minor grains in Zhejiang Province is low, the main reason being a lack of superior varieties and good methods of growing them. The same old varieties and the same old techniques are used in most fields. The Lanqi County Institute of Agricultural Sciences used superior varieties and superior methods in combination to grow autumn soybeans, harvesting yields of 481 jin per mu, more than double the yield from the growing of soybeans generally. Everyone acknowledged that through experience in production all jurisdictions in Zhejiang Province have bred group of superior varieties of minor grain crops suited for promotion locally. In recent years quite a few superior varieties have been introduced from elsewhere. One such is superior soybean variety, Aijiaozao, which ripens early, produces high yields, has fine quality beans, tolerates fertilizer, tolerates cold, and tolerates delayed planting. Another is superior peanut variety, Yueyou 551, which produces consistently high yields, has a quite good flavor, and produces yields that range from 30 to 50 percent higher than local varieties. Wuyuekui variety of sunflowers is another superior variety. It has short stems and ripens early, has a large disc that produces high yields, tolerates fertilizer, poor soil, salinity and alkalinity, and is suited for growing over a wide area. Active promotion of these superior varieties can bring about a new situation in output of minor grains in Zhejiang Province.

BRIEFS

FARM MACHINE INDUSTRY PLANS MET EARLY--The farm machinery industry in Zhejiang Province has overfullfilled quotas for the entire year 1 month ahead of schedule. This year farm machinery industry departments responsible organized a group of key enterprises for a thoroughgoing investigation in rural villages to find out peasant needs and to understand what new situations had arisen in joint use of farm machinery by households, rentals of farm machinery by communes and brigades, and individual purchases of farm machinery following the advent of specialized contracting and linking calculation of remuneration to output in agriculture. Overall requirements for farm machines are, first, that they be small, second, that they be good, and third, that they do not cost much money. Acting on the basis of these new requirements, each plant provided for the production of a group of small farm machines, increased output of hand tractors, tea processing machines, small power machines, threshing machines, and machines that can be pushed by hand. Once they reached rural markets, they became goods in great demand. Acting on the basis of export demand, each plant increased output of new varieties for export, the province;s farm machinery exports increasing from six or seven kinds to more than 20 kinds, and the volume of business increasing twofold over last year. TITLE: " New Method of Raising Pigs for Fast Weight Gain"

SOURCE: Changchun NONGCUN KEXUE SHIYAN [RURAL SCIENTIFIC EXPERIMENTS] in Chinese No 1, 1 Jan 82 p 5

ABSTRACT: ZHU Xiaowen [2612 2556 2429] a member of Huaijia Commune of Yushu County raised 2 sows in early 1981 and obtained 23 piglets. He sold 13 piglets and 1 sow in Apr; in May and Oct he again sold 15 pigs to the state. In the year, he earned an income from raising pigs a total of 3,468 yuan and still had 14 piglets in his sty. The secret of his success is summarily reported as follows: (1) Giving the pigs raw green feed instead of cooked feed he saves more than 14 yuan per pig in fuel and 30 percent of the labor and the raw feed is better for the pigs. (2) Instead of one kind of feed, he mixes green, coarse, and fine feed in a proper ratio to satisfy the nutritional needs of the pigs. (3) The dry feed is mixed with water to form a gluey paste which pigs are very fond of. (4) Due to the fact that the pasty feed is very digestible, he feeds the pigs 5 times instead of 3 times a day. (5) His piglets do not lose weight after being weaned. They are cared for very specially by giving no less than 0.5-1 jin a day of processed feed in the daily diet. By summer time, a large quantity of green feed is added until the pig grows to weigh 140-150 jin before adjusting the feed by adding more processed feed to fatten it for about 2 months. By then, the pig weighs more than 200 jin and is ready to be sold as a commercial hog.

TITLE: "Raise a Large Number of Small Donkeys"

SOURCE: Changchun NONGCUN KEXUE SHIYAN [RURAL SCIENTIFIC EXPERIMENTS] in Chinese No 1, 1 Jan 82 p 16

ABSTRACT: This paper discusses the virtues of a species of small Chinese donkeys, called Maolu. They are not very big but they can pull about 250 kg of weight and are capable of working the field, transporting the harvest, or pumping the water. They are very gentle and willing to perform hard work; they tolerate coarse feed and are disease resistant. They are skillful in maneuvering the small trails. Their meat has a high protein content and is easily digestible by men. Their hide is a raw material for a traditional Chinese drug and can also be made into a high grade leather. All these excellent characteristics also cause them to be good beasts of burden, particularly useful in the military. The cost of raising them is low. In Nongan County, for example, more than 17,000 heads were raised in one year. In Nei Monggol, there were 7373 heads of animals sold on the market and 5021 of these were donkeys of this species. The price of other animals is reported to be 10 percent higher this year, but that of the small donkey has risen 30 percent. The need for these donkeys is definitely related to the development of China's rural economy and their rise in price signals the improved condition of rural production.

TITLE: "Preliminary Research on Effect of Inducing Male Sterility in Kenaf by Chemicals"

ABSTRACT: Changsha ZHONGGUO MAZUO [FIBER CROPS IN CHINA] in Chinese No 3, Jul 81 pp 21-26, 20, 9

ABSTRACT: Hybrid kenaf [ambary] F_1 demonstrates obvious heterosis but at present there is yet no effective seed preparation method. According to foreign reports, treatment with 0.01-0.05 percent Embutox can produce partial male sterility. In 1979-80, the authors conducted an experiment to test the effects of dichloropropanoic acid and dalapon. Effects of these 2 chemicals are compared with those of other chemicals, such as CK, FW-450, AW-0, KMS-1, MH, etc. Effects of the chemicals on the growth of the kenaf plants and the development of their reproductive organs are observed. The male sterility effect is found to be closely related to the density of the chemical used, and the amount, timing, and number of spraying. The effect is also easily influenced by environmental factors. Analysis of experimental data also indicates that the amount of chemical accumulated in the plant is directly related to the detasseling action. As the effective content of the chemi-

[continuation of ZHONGGUO MAZUO No 3, 1981 pp 21-26, 20, 9]

cal increases, the effect of male sterility is higher, and the fruiting rate of artificial pollination is also reduced, i.e. there is less number of seeds in each plant. Is this a problem of too much chemical content in the plant body to cause an effect on the pistil itself? Or is it an effect on the fertilization process? Further study is needed to answer these questions.

TITLE: "Proper Sowing Time Makes Higher Yield and Finer Quality of Flax Fiber"

SOURCE: Changsha ZHONGGUO MAZUO [FIBER CROPS IN CHINA] in Chinese No 3, Jul 81 pp 47-48

ABSTRACT: The growth and development period of flax [Linum usilatissimum] is short and it is a crop requiring a great deal of water. When there is no condition for irrigation, the effective measure for improving the yield and the quality of flax is to grasp the proper time for planting. A research on the proper sowing time for flax began in 1963 and in 1965 the sowing time was proposed to be moved from late Apr to early May, resulting in 33.9 percent yield increase in 1966. In 1978-79, a 2-year experiment again proved that the yield and quality of flax are the best when the sowing time is from late Apr to early May. This is mainly because when it is planted during that period of time, the flax can best utilize the favorable condition of nature during its growth and development period. When it is planted earlier, the fiber quality is good, but the drought may easily stunt the plant to produce a low yield. When it is planted too late, the high temperature and frequent rain are favorable for the growth of the stalk but not favorable for formation and accumulation of fiber to result in a low yield of poor quality fiber.

TITLE: "Forests - A Green Shield Against Floods"

SOURCE: Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 1, 1982 pp 2-3

ABSTRACT: In the 2 months of Jul and Aug 81, tremendous rain storms fell onto the 195,000 m^2 of superior cropland, causing unprecedented floods in the 135 counties of the Sichuan Basin. Some say this is a natural calamity but generally speaking although changes of atmospheric circulation are the basic condition of rain storms the depreciation of forest coverage remains the direct cause of the overwhelming damage. This paper explains the fact that forests can store moisture, change the distribution ratio of rainfall, and regulate the speed of water flow; therefore, they control and weaken the power of floods. For example, in Cangqi County, the forest cover is more than 30 percent. After 241 mm of rain, the ground surface stream coefficient was 42.6 percent. In Nanchong and Wusheng Counties, there was only 111 mm of rain, but the stream coefficient was 68.1 percent because the forest cover was only 2-6 percent. This disastrous flood of Sichuan should serve as a lesson to remind the people the benefits of forests.

TITLE: "The Method of Controlling and Promoting According to the Leaf-age Indices of Wheat"

SOURCE: Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 1, 1982 pp 8-9

ABSTRACT: Many studies have been conducted and many papers written on the subject of obtaining high and stable yield of wheat, while reducing the cost, the labor, etc. but there was still no concrete standard to follow. The leaf-age technique provides a scientific method of management to standardize water and fertilizer applications of the wheat fields. A drawing is given to depict 3 leaf-ages signaling the time to apply fertilizer and water. Since 1980, the technique has been extended in Beijing, Hebei, Shanxi, Shandong, Tianjin, etc. in 1.15 million mu of wheat fields. In Xincheng County of Hebei, for example, for the 57,107 mu of wheat, after adoption of the technique, the average yield increase per mu has been 49.7 jin, at a cost reduction of .0215 yuan per jin. The total cost reduction was 56,810 yuan and the increased yield was valued at 422,776 yuan. The technique is described in some detail.

TITLE: "Talking About Humus Fertilizer"

SOURCE: Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 1, 1982 p 17

ABSTRACT: In the past, Chinese farmers often used such black colored fertilizer as silt, lignite, peat moss, etc. All these are humus fertilizers containing humic acid. Now many humic acid containing materials are used to process with nitrogen, phosphorus, potassium, or trace elements to produce mixed fertilizer. If humic acid is mixed with ground phosphate rock, there is very little improvement of phosphorus utilization, only about 0.166 percent in the entire growth and development period of rice, but such humic acid phosphorus fertilizer is effective for rape and buckwheat. Humic acid can also improve the absorption of potassium fertilizer by crops and has a chelating action to produce chelates with some hard-to-dissolve trace elements to cause them to be easily absorbed by plants.

TITLE: "Soil Treatment With Phoxim for Controlling Northeast Large Black Chafers"

SOURCE: Harbin HEILONGJIANG LINYE [HEILONGJIANG FORESTRY] in Chinese No 2, 5 Feb 82 pp 10-12

ABSTRACT: Large black chafers [scarabaeid beetles] are not only the major pests of agriculture. They also inflict major damage to the production of saplings in the Northeast. In 1980, of the 70 mu of saplings of various pines cultivated by the Dongfeng Commune, these beetles destroyed more than 20 mu, at a loss of 5 million young trees worth nearly 50 thousand yuan. In 1981, the authors conducted an experiment in 6 groups of plots. In 4 groups, 0.5, 1, 2, and 3 jin/mu of phoxim (in 50 percent emulsion, a product of Tianjin Pesticide Plant) is mixed with water and evenly sprayed in trenches of the seedbed before adding soil to the trenches to restore the leveled surface. In the 5th group, 1.5 jin/mu of phoxim is used. The 6th group forms the control. Results of the experiment indicate that for controlling such underground pests as the chafer, 1-1.5 jin/mu of phoxim diluted in water and applied to the 3-5 cm topsoil is very effective. This soil treatment should be done 3 to 5 days before planting. The beetle-killing effect of phoxim lasts about 3 months and a few larvae will survive to pupate at about 20 cm below the level of the phoxim application; therefore, for effective control, it is best to apply 2 years consecutively.

TITLE: "Photosynthetic Characteristics of a Yellow-green Rice Mutant"

SOURCE: Kunming YUNNAN ZHIWU YANJIU [ACTA BOTANICA YUNNANICA] in Chinese No 4, Nov 81 pp 449-456

TEXT OF ENGLISH ABSTRACT: This paper concerns the photosynthetic characteristics of a yellow-green nucleus mutant of rice which was obtained by us in anther culture. The content of total chlorophyll, xanthophyll and β-carotene in the mutant leaves is about 31 percent, 40 percent and 75 percent of that in normal leaves respectively; the chl a/chl b ratio of the mutant is much higher than that of normal leaves. The analysis of SDS-solubilized extracts of the chloroplast lamellae shows that the major light-harvesting chl a/b protein complex of the mutant is extremely deficient, and its chl a/chl b ratio is more than 3. In the chloroplasts of mutant leaves, there are very few grana stacking, and more starch grains can be seen when leaves are exposed to sunlight. The rate of CO_2 assimilation of mutant leaves exposed to 20,000 lux of sunlight is 75 percent of that of normal leaves on the basis of leaf area, and is 185 percent based on chlorophyll. The chloroplasts of the mutant may also show a much higher rate of ferricyanide Hill reaction based on chlorophyll.

[Continuation of YUNNAN ZHIWU YANJIU No 4, Nov 81 pp 449-456]

The results show that the grana stacking of chloroplast is closely related to the quantity of the light-harvesting chl a/b protein, and is not essential for the photosynthesis process.

TITLE: "The Preliminary Studies on Culture of Unfertilized Rice Ovary *In Vitro*"

SOURCE: Beijing ZHIWU XUEBAO [ACTA BOTANICA SINICA] in Chinese No 1, Jan 82 pp 33-38

TEXT OF ENGLISH ABSTRACT: The present paper reports the results of the culture of unfertilized ovaries of rice *in vitro*. The inducting medium was N_6 supplemented with 2 mg/l 2,4-D, 500 mg/l casien hydrolysate and sucrose was 4 percent. The differentiated medium was N_6 supplemented with 2 mg/l Kinetin, 500 mg/l casein hydrolysate and the concentration of sucrose was 3 percent. The four cultivars and two crossed combinations were used as the experimental materials. The experiments showed the differentiation of the callus which occurred among various cultivars. The induced frequency in the crossed combinations was higher than that in the cultivars. Now 12 green plants and 3 albino plantlets have been obtained. The chromosomes of 11 green plantlets have been examined. Among them, six plantlets were haploid ($n = 12$) and five plantlets were diploid. The embryoids were located in the micropylar end. Some of them possessed the suspensor, similar to zygote embryos. The callus was found to be from different origins. One of them originated from haploid tissue derived from the nucleus in the embryo sac. Another originated from the diploid tissue in the integument or ovary wall. The origin of the callus from the unfertilized ovary was discussed.

TITLE: "Comparative Studies of Some Kinetic Properties of Glyceraldehyde 3-Phosphate Dehydrogenase and Fructose-bisphosphatase in Chloroplasts from Wheat and Rice"

SOURCE: Beijing ZHIWU XUEBAO [ACTA BOTANICA SINICA] in Chinese No 1, Jan 82 pp 39-45

TEXT OF ENGLISH ABSTRACT: Enzymatic properties of the chloroplast GAP dehydrogenase and FBPase from the wheat or rice leaves of the main stems during the grain filling period have been investigated. According to the effect of the substrate or coenzymes concentration, it is shown that the GAP dehydrogenases in freshly ruptured wheat or rice chloroplast show higher activities than FBPase, especially the activity of the wheat chloroplast GAP dehydrogenase which is over 10 times greater than that of FBPase. However, the activities of the above two enzymes in the rice chloroplast show only a little difference, with the activity of the rice FBPase being higher than that of the wheat.

The maximum initial velocities (Vmax) of the two enzymes in the above two chloroplasts are determined and are apparently different from each other.

[Continuation of ZHIWU XUEBAO No 1, Jan 82 pp 39-45]

At about 0.2 mM NAD(P)H concentration the activity of GAP dehydrogenase in the rice chloroplast is saturated. But, with the same concentration, the wheat GAP dehydrogenase is still not saturated. It is noteworthy that the ratio of the activities of the two chloroplast GAP dehydrogenases for NADPH and NADH approaches equality as the coenzyme concentration is increased.

Possible physiological significance of the kinetic properties of the above two enzymes during the wheat and rice grain filling period is discussed.

TITLE: "Studies on the Overwintering Limit of Brown Planthopper in China"

SOURCE: Beijing KUNCHONG ZHISHI [ENTOMOLOGICAL KNOWLEDGE] in Chinese No 1, Jan 82 pp 1-5

ABSTRACT: As a part of the study on the migration principle of brown planthopper feeding on rice (Nilaparvata lugens Stål), the group have carried out several years of investigation and experimentation to answer such questions as whether the planthopper is capable of overwintering within the territory of China, what is the ecological condition of overwintering, what is the form of the overwintering insect, etc. Due to the fact that paddy rice is the only food of the brown planthopper and it is unable to withstand very low temperature, the work has been carried out mainly in Guangdong, Guangxi, Fujian, Hunan, Jiangxi, Yunnan, and Guizhou provinces. Analyses of data of 1975-79 appear to indicate that the overwintering limit is closely related to the mean temperature of the month of January; therefore, the northern limit fluctuates between 21° and 25°N.Lat. The survival rate and the temperature are in a linear relationship, being 0.40 (40 percent) if the mean temperature of January is 11°C.

TITLE: "Preliminary Report on the Late Rice Seedings Infested by Stolia ventralis (Westwood)"

SOURCE: Beijing KUNCHONG ZHISHI [ENTOMOLOGICAL KNOWLEDGE] in Chinese No 1, Jan 82 pp 5-7

ABSTRACT: Black shieldbugs (Stollia ventralis) (Westwood) are common pests in China damaging not only rice but also gaoliang, corn, millet, beans, and cotton. In the last 2 years, it had become the major pest of late rice seedlings in Dasha Commune, of Sihui County. That commune had had the practice of applying large quantities of pesticides during the late stage of early rice and the seedling stage of late rice, which is the peak of propagation of the shieldbugs; therefore, this pest had not been very noticeable. Now that the comprehensive control policy has been launched and less pesticide is used, this pest grows into a gigantic population. After the early rice harvest, most adults move to nearby late rice seedbeds. Following a study of its morphology and life history, the paper recommends a mixture of malathion and DDT for its control. Protection of its natural enemies, including frogs, spiders, ants, etc. is also a meaningful measure of its control, of course.

TITLE: "The 5HZ-3.2 Grain Drying Machine"

SOURCE: Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 1, 1982 p 9

ABSTRACT: Properly dried seeds are the key to high yield. In the past, seeds are dried in the sun, depending upon constant turning. The drying process takes a long time and considerable labor, while the seeds are not evenly dried and easily mix with foreign matter to reduce their quality. For this reason, the Chinese Academy of Agricultural Sciences, the Shanghai Municipal Institute of Agricultural Machinery, the Sichuan Provincial Institute of Agricultural Machinery, the Sichuan Yongchuan General Machinery Plant, and the Santai County Agricultural Machinery Repair Plant cooperated in the research and manufacture of the 5HZ-3.2 seed dryer. The new product was certified by the ministry in Nov 81. It is suitable for seed companies, communes, and brigades to dry rice or wheat seeds. It may also be used to dry commercial grain. The structure of the machine is described, including a brief drawing of the machine. The cost of electric power is about 0.50 yuan/ton. Compared with similar domestic products, its properties are judged to be advanced.

TITLE: "Studies on the Characteristics of Nitrogen Supply in Paddy Soils. II. Effect of Fertilization on the Soil Nitrogen Supply and Grain Yield of Double Cropping Rice"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 1, Feb 82 pp 13-21

TEXT OF ENGLISH ABSTRACT: Field trials and micro-plot experiments using ^{15}N-labeled ammonium sulfate were conducted on a silty clay paddy soil developed on alluvial deposits of the Hangzhou Bay.

The experiments with the same design for early rice and late rice were laid out separately in the same field for comparative investigation. The results obtained are summarized as follows:
(1) The A-value of the soil and the amount of soil N assimilated by the late rice were considerably higher than those of the early rice, which may be mainly due to the difference in temperature regime between the two growing seasons. The amount of N taken up by the late rice was 3.66 - 4.18 percent of the total N content in

[Continuation of TURANG XUEBAO No 1, Feb 82 pp 13-21]

the plowed layer, and was only 2.69 - 3.21 percent for the early rice. Correspondingly, the grain yield of the late rice in the control plot was much higher than that of the early rice.
(2) Soil N was the predominant source of the total N accumulated in either early rice or late rice. In the treatments of organic manure and chemical fertilizer, the percentage of soil-derived N in the total assimilated N of the double-cropping rice ranged from 48.6 - 81.4 percent, while the fertilizer-N and manure-N were 14.3 - 40.3 percent and 11.1 - 19.6 percent respectively.
(3) The percentage of soil-derived N in the total N accumulation in different organs tended to decrease in the order of roots, shoots and panicles, and the reverse was true for the fertilizer-N.
(4) Under the same method of application of nitrogen fertilizer, there was no significant difference in N recovery from ^{15}N-labeled ammonium sulfate by early rice or late rice, their recovery percentages being 28.8 - 35.5 percent and 28.3 - 31.2 percent respectively. However, the efficiency of the fertilizer on increasing the grain yield of early rice was much lower than that of late rice. This may be due to the different soil N supplying capacity in different growing seasons. Around 65 percent of the assimilated fertilizer-N was distributed in panicles, which might be related to the higher efficiency of nitrogen fertilizer applied at the panicle formation stage.
(5) Under the same method and rate of application of pig manure, the N recovery by late rice was higher than that by early rice. The highest grain yield of early rice

[Continuation of TURANG XUEBAO No 1, Feb 82 pp 13-21]

and late rice was obtained by the treatment of the application of pig manure in combination with ammonium sulfate, which may imply the consistency of nitrogen supplying status in the soil of this treatment with the demand of rice.

TITLE: "Studies on Soil Particles in China. I. Some Physical and Chemical Properties of Soil Particles in Different Size Fractions of the 'Whitish Horizon' in Bleached Paddy Soil of Tai Lake Basin"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 1, Feb 82 pp 22-33

TEXT OF ENGLISH ABSTRACT: The soil particles of the "whitish horizon" in bleached paddy soil were separated into seven fractions (1 - 0.25, 0.25 - 0.05, 0.05 - 0.01, 0.01 - 0.005, 0.005 - 0.002, 0.002 - 0.001 and < 0.001 mm). Chemical analysis showed that the sand fraction (1 - 0.05 mm) in which there are "iron-manganese sands" contained less SiO_2 and more Fe_2O_3 than the silt fraction (0.05 - 0.002 mm). The sand fraction was characterized by its very high magnetic susceptibility. Its hygroscopic coefficient was also higher than that of the silt fraction by 3.5 - 4.0 percent. These features of the soil are different from those of the upland soils. This implies that in addition to SiO_2, other minerals may also be present in the sand fraction.

[Continuation of TURANG XUEBAO No 1, Feb 82 pp 22-33]

Experimental results confirmed that it was only the clay fraction (<0.002 mm) which could exhibit plasticity and swelling properties. The plastic index and swelling capacity of the fine clay (<0.001 mm) were higher than those of the coarse clay (0.002 - 0.001 mm) by 2-3 times. The compressive strength of the silt fraction was very low (0.014 - 0.147 Kg/cm^2), but its bulk density in water was greater (1.37 - 1.42 g/cm^3). Under waterlogged conditions, the silt fraction settled down as a compacted layer. The settling and compacting of the "whitish horizon" might be mainly affected by the content of coarse silt (0.05 - 0.01 mm) and the ratio between coarse silt and fine clay.

It is considered that the critical limits for a soil to exhibit settling and compacting properties are: coarse silt content $\geq$ 40 percent, ratio between coarse silt and fine clay content $\geq$ 2, and the organic matter content $\leq$ 2 percent.

TITLE: "Formation and Reclamation of Tile-like Crust-solonetz"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 1, Feb 82 pp 34-42

TEXT OF ENGLISH ABSTRACT: The present paper deals with the formation and reclamation of tile-like crust-solonetz in the semi-arid region of China.

The main characteristics of tile-like solonetz are given as follows: 1. There are no plants except alkali-tolerant plants on this soil. 2. On the surface of the soil there are tile-like crusts of 1-2 cm in depth; and on the crust back there are spongy structures. 3. The total salt content of the soil is not so high in the whole profile, that of the surface soil is less than 0.5 percent, and that of the subsoil is 0.1 percent. Sodium carbonate and sodium bicarbonate are predominant in salt composition. The pH of the entire soil profile is above 9 and ESP is higher than 20 percent.

[Continuation of TURANG XUEBAO No 1, Feb 82 pp 34-42]

Soil survey and the modeling test in the laboratory has proved that there are two different ways by which the crust-solonetz is formed. First, in the process of alternation of accumulation and desalination, the sodium ions enter the soil adsorptive complex in the salt-affected soil containing sodium salt. Second, the salt is alkalized with the accumulation of sodium-carbonate and bicarbonate in soil induced by the rising of the low mineralized ground water.

This soil should be improved with integrated measures. In the area where there are conditions of irrigation and drainage, agricultural measures, such as deep plowing combined with the application of a large amount of organic manure, may be adopted. However in the area where the soil is more highly alkalized, chemical measures, such as application of gypsum or phospho-gypsum, should be adopted in addition to the agricultural measures.

TITLE: "Soil Colloid Research. VIII. The Mineralogical Composition of the Colloids of Five Important Soils in China."

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 1, Feb 82 pp 62-70

TEXT OF ENGLISH ABSTRACT: The mineralogical composition of the soil colloids separated from black soil, loessial soil, yellow brown earth, red earth and laterite have been quantitatively analyzed by the systematic method of Alexiades and Jackson. In order to have the determination of the mineralogical composition of soil colloid more suitable for the actual conditions of these soils, the analytical methods of kaolinite and illite have been modified. The content of kaolinite was determined by NH_4Cl retention measurement instead of selective dissolution analysis. For estimating the content of illite, 5 percent of the K_2O extracted by 1 N HNO_3 was regarded as a parameter. The content of mica was calculated by means of 10 percent of the amount of total K_2O subtracting the K_2O extracted by 1 N HNO_3.

[Continuation of TURANG XUEBAO No 1, Feb 82 pp 62-70]

The composition of the clay minerals of the five soils varies greatly. The highest content of montmorillonite is found in black soil, and its decreases gradually from north to south. However, the content of kaolinite tends to increase gradually from north to south. Vermiculite and transitional minerals of 14 Å are found in the soils of subtropical China.

TITLE: "Micromorphological Characteristics of Some Cultivated Soils in Northeastern China"

SOURCE: Beijing TURANG XUEBAO [ACTA PEDOLOGICA SINICA] in Chinese No 1, Feb 82 pp 85-91

TEXT OF ENGLISH ABSTRACT: Micromorphological characteristics of black soils, planosols and soda-solonchaks of various levels of fertility were investigated by means of structure analysis, optical microscopy and scanning electron microscopy. The results obtained are summarized as follows:

1. With a large amount of humic substances, black soils are well aggregated and highly stable in structure. The content of microaggregates (> 0.05 mm) in black soils is about 30-70 percent, that in planosols is less than 30 percent, that in unimproved soda-solonchak is 20 percent, and that in ameliorated soda-solonchak is 46 percent. The water-stable aggregates (> 0.25 mm) are distributed with the same tendency of the microaggregates (> 0.05 mm) in the soils.

2. Under a microscope, the degree of aggregation and the size of soil microaggregates, as well as soil porosity, can be observed precisely. Black soils have

[Continuation of TURANG XUEBAO No 1, Feb 82 pp 85-91]

a spongy fabric. Soil particles are cemented by gel-like substances to form porous soil structure. Planosols show a loosely-bound agglomeratic fabric with lower porosity. Unimproved soda-solonchaks belong to a porphyropeptic fabric in which almost no aggregates can be found. The ameliorated soda-solonchaks have a plucto-amictic fabric in which microaggregates are formed by the gel-like substances and mineral grains.

3. The variation of the organo-mineral complexes in soils is also observed by a scanning electron microscope. In fertile black soils the organo-mineral complexes are agglutinated by the gel-like substances to form a loose and soft soil structure. In unimproved soda-solonchaks and planosols the particles are merely accumulated together without any evidence of cementation. In ameliorated soda-solonchaks some gel-like substances appear on the particle surface, which means organo-mineral complexes are formed.

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 10, 20 Oct 81 pp 11-15

ABSTRACT: Since 1966, a disease of unknown origin with hematuria as the primary symptom has been occurring in pigs in some areas of Ningqiang, Lyuyang, Yangxian, and Mianxian counties of Shaanxi Province. The incidence is growing. The authors began to carry out a survey of this disease in 1975 to learn its distribution, its natural environment, the feeding and management condition, etc. In the process, leptospirosis and other infectious diseases were gradually excluded. Through a feeding experiment, it was discovered that the local people had the habit of feeding the pigs with a local plant called Xiaopaoye, which was subsequently identified to be Discocleidion rufescens (Franch.) Pax et Hoffm. This plant was experimentally fed to a pig and it developed hematuria with all signs and dissection changes identical to those pigs which developed the disease naturally. The disease is, therefore, proved to be a toxic reaction to a poisonous plant. Clinical symptoms, microbiological and serological reactions, treatment method and results, and toxicological analysis of the poisonous plant are reported.

TITLE: "Research on Weakened Bovine Paratyphoid Vaccine"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 11, 20 Nov 81 pp 7-8

ABSTRACT: There have been extensive epidemics of bovine paratyphoid fever in the prefecture and the province causing death to large number of calves and some adult oxen as well. The pathogen is primarily Salmonella bovis morbificans . At present, the live vaccine with aluminum hydroxide added has produced obvious effects but the immune period is too short and the vaccine has to be injected. The authors cultured a strain, S7301, obtained from a diseased ox to produce the S7301-738 vaccine without adding other agents. Used in a mist, the vaccine has been found to be effective and safe for calves and it does not appear to have obvious adverse effects on the workers who handle the mist.

This paper was received for publication on 4 Sep 80.

TITLE: "Listeria monocytogenes Found in Swine Cholera Victims: A Diagnostic Report"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 11, 20 Nov 81 pp 13-15

ABSTRACT: Swine cholera has been endemic for the experimental pig farm of the school. In 1978, more than 20 piglets died of it. In May 80, 15 newly weaned piglets came down with the disease and bacteriological examination of 3 of these produced Listeria monocytogenes. The major expression of listeriosis is septicemia which is also the major symptom of swine cholera. It is, therefore, clinically difficult to distinguish. Correct diagnosis is possible only through bacteriological examination. Massive doses of penicillin and streptomycin can be effective for listeriosis at the very early stage if it is diagnosed early and correctly.

TITLE: "Preliminary Electromicroscopic Observation of Liver and Muscle of Piglets of White Muscle Disease"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 1, 20 Jan 82 p 2, inside front cover

ABSTRACT: White muscle disease occurs extensively among the piglets in China, especially in the Northeast. In 1979, the authors discovered a general phenomenon of low selenium level in pig livers of that region, only about 0.11 ± 0.026 ppm (dry weight.) In 1980, they conducted an epidemiological study of this disease in several farms of Dedu County, to observe the clinical symptoms of piglets, to take EKG's to carry out hematological analysis, and to determine the selenium content. Moreover, for the piglets of the disease, electromicroscopic observation of the liver and the skeletal muscles was performed. Liver cells are observed to be obviously turning into fat; myofibrillae appear to turn angular. Photo-illustrations of these and other findings are reproduced on the inside front cover of this issue.

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 1, 20 Jan 82 pp 36-41

ABSTRACT: Following a general discourse on mycology and the outstanding problem of definition of the term, mold, in China, this paper examines the following in separate sections: (1) Animal diseases caused by fungus poison; (2) Veterinary mycosis; (3) Medicinal fungi; (4) Production of fungal protein for feed, the value of its utilization, and the problem of toxicity. Responsibilities of veterinary mycological research in China are summarized in the following: (1) Diseases of fungus poison; (2) Mycosis; (3) Fungus feed; (4) Medicinal fungi.

TITLE: "Harmful Effects of Nitrate and Nitrite Accumulations in Green Feed on Animals and Their Control"

SOURCE: Lanzhou SHOUYI KEJI ZAZHI [JOURNAL OF VETERINARY SCIENCE AND TECHNOLOGY] in Chinese No 1, 20 Jan 82 pp 42-47

ABSTRACT: The extensive and pervasive existence of nitrates and nitrites in plants, the air, the soil, and the drinking water and their danger to men and animals have gradually been brought to the attention of related departments. This paper explains the absorption of nitrates by crops and grass for the synthesis of vegetable protein while microbes in the stomach of animals reduce the nitrates into nitrites, which are antecedents to the carcinogenic nitrosamine. Applications of large quantities of nitrogen fertilizer and the use of hormone herbicides, unreasonable irrigation with industrial wastewater, excessively dense planting causing insufficient solar radiation on crops, etc. further aggravate the problem. Some data concerning the relationship between the nitrate content of spinach and beets and the quantity of fertilizer applied and light penetration, the NO_2^-, NO_3^- contents of several vegetables and forage grass are given, but not the origin of the information. Harmful effects of nitrates and nitrites on animals are explained in some detail. There is a table explaining the relationship between the nitrate content of feed and the

[continuation of SHOUYI KEJI ZAZHI No 1, 1982 pp 42-47]

hemoglobin and methemoglobin contents of the blood of dairy cows [from an unspecified source of USSR.] Aside from methemoglobinemia, the symptoms of acute poison by nitrites, the carcinogenic action of nitrosamines, and harmful effects of nitrites in the digestive tract on preventing the formation and absorption of vitamin A, D, and E are briefly discussed. The need for molybdenum fertilizer in many parts of China, careful storage of green feed to control its temperature and freshness, and the protection of the natural environment against pollution are recommended as essential for controlling the harmful effects of nitrates and nitrites. There is no mention of Chinese studies on the subject in the paper.

TITLE: "Faunal Analysis of the Agricultural Insects in Jiangxi Province"

SOURCE: Kunming DONGWUXUE YANJIU [ZOOLOGICAL RESEARCH] in Chinese No 1, Feb 82 pp 31-35

TEXT OF ENGLISH ABSTRACT: This paper deals with the faunal analysis of 1,100 species of agricultural insects, including the pests and their enemies. The present paper is divided into two parts: the first part introduces the types of fauna of the insects and the percentage of each type, and the second illustrates the names of the species whose south or north border of distribution is within Jiangxi and indicates their south or north distributional lines.

Among these insects, a total of 48.82 percent belongs to the faunal of the Oriental region, and 16.91 percent are of the palaearctic region. If all of the "Orientals" are summed up, the percentage will increase to 81.64 percent, and "palaearctics" will increase to 43.46 percent, so it is safe to say that Jiangxi belongs to the fauna of the Oriental region and is near the southern border of the Palaearctic region.

TITLE: "A Report on the Mammals of Ankang Region, Shanxi Province"

SOURCE: Kunming DONGWUXUE YANJIU [ZOOLOGICAL RESEARCH] in Chinese No 1, Feb 82 pp 59-68

TEXT OF ENGLISH ABSTRACT: A faunal survey was conducted from April 1963 to February 1966 in the Ankang region of the southern part of Shanxi Province. Collections were made at the following localities: Ningshan, Shiquan, Hanyin, Ankang, Xunyang, Lan'gao, Pingli, Baihe, Ziyang and Zhenping. Altogether, 2989 specimens were collected, including 96 species and subspecies belonging to 26 families and 7 orders.

This region, in the authors' view, may be zoogeographically divided into six zones:
1. Subalpine coniferous forest zone of Qinling (altitude above 2500 m);
2. Mid-mountain mixed forest zone of Qinling (altitude 2500-1300 m);
3. Low mountain defoliation and broad leaf and even green broad leaf forest zone of Qinling (altitude 1500-800 m);
4. Cultivated field zone of Ankang Basin (altitude 800-500 m);

[Continuation of DONGWUXUE YANJIU No 1, Feb 82 pp 59-68]

5. Low mountain even green defoliation and broad leaf forest zone of Taibai Shan Mountain (altitude 2000-1300 m);
6. Subalpine coniferous forest zone of Taibai Shan Mountain (altitude above 2200 m).
For each of these zones, brief notes are given concerning its faunal characteristics, with due emphasis on representative species.

On the south slope of Qinling, 27 percent of the mammals are Palaearctic species, 44 percent are Oriental species. On the north slope of Taibai Shan Mountain, almost 15 percent of the mammals are Palaearctic species and 47 percent are Oriental species.

From the above analysis, the authors conclude that Qinling Mountain, along with Taibai Shan region, is apparently a transitional belt between the Palaearctic and Oriental realms. The oriental elements are increasing from north to south, while the palaearctic ones are decreasing gradually.

EXCERPTS FROM ENGLISH ABSTRACT: A survey of parasitic nematodes in domestic animals and poultry of Lingling area, Hunan Province, was made during June-July, 1979. After an examination of 154 livestock and poultry, 47 species belonging to 18 families and 30 genera and including two new species and three new records for China were found. The new species are described in this paper and type specimens are deposited in the Institute of Animal Husbandry and Veterinary Science, Hunan.

The new species are:
Elaeophora linglingense sp. nov.
Types: Holotype ♂, allotype ♀, paratypes 6 ♀♀ .
Host: Cattle
Location: Wall of aortic arch.
Locality: Lingling County, Hunan Province, China.

TITLE: "A Survey of the Cestodes of Birds from Weishan Lake, Shandong Province, China"

SOURCE: Beijing DONGWU FENLEI XUEBAO [ACTA ZOOTAXONOMICA SINICA] in Chinese No 1, Jan 82 pp 27-31

EXCERPT FROM ENGLISH ABSTRACT: The material was collected from both wild birds and poultry in the region of Weishan Lake from November to December, 1975. Through an examination of 137 wild birds belonging to 15 species, 103 (75.1 percent) individuals were found to be infected with cestodes. Ten species of parasitic cestodes belonging to seven genera of the family Hymenolepididae have been identified and enumerated on in the Chinese text. In addition, an examination of 16 ducks and 9 fowls revealed the presence of 2 species of cestodes: *Fimbriaria fasciolaris* (Pallas, 1781), and one new species which is described. It is:
Retinometra chinensis, sp. nov.
Host: Domestic duck.
Location: Small intestine.
Locality: Weishan Lake, Shandong Province, China.

I. GENERAL INFORMATION

FIVE AUTONOMOUS REGIONS ACHIEVE BUMPER HARVESTS

Beijing ZHONGGUO NONGMIN BAO in Chinese 17 Jan 82 p 1

[Article by Zhang Ru [1728 0320]: "Implementing the Party's Farm Village Policy and National Minority Policy, Five Autonomous Regions Realized Bumper Harvests in Agriculture and Livestock Production Last Year"]

[Text] Combined report: Because the party's farm village policies and the national minority policies were further implemented and because science and technology were actively popularized, our nation's five national minority autonomous regions--Nei Monggol, Ningxia, Xinjinag, Xizang and Guangxi--overcame many natural disasters and realized bumper harvests in agriculture and livestock production in 1981.

Nei Monggol: Agriculture realized overall bumper harvests. The sowing area of food grains decreased by more than 630,000 mu from 1980, but the total yield increased by more than 2 billion jin, surpassing the highest level in history. Oil-bearing crops and sugar-yielding crops increased 16 percent and 18.8 percent respectively over 1980. Two years ago, the "production teams that relied on three commodities," which constituted one-third of the total number of production teams of the whole region, basically solved the problems of a shortage of food and clothing. The per capita average income of commune members in farm villages throughout the region is estimated at 215 to 220 yuan, an increase of more than 30 yuan over 1980.

Livestock production was seriously affected by drought in 1981, but the number of livestock still approached the number alive the previous year. The per capita income of the herdsmen of the whole region surpassed 300 yuan, an increase of more than 40 yuan over 1980.

Ningxia: In the more than 30 years since the founding of the nation, food grain production in Ningxia surpassed 2 billion jin in only 6 years. Four of these years were after the Third Plenum. During the past 2 years, it reached above 2.4 billion jin. Oil-bearing crops and sugar-yielding crops increased by a large amount, changing the long practice of importing edible oil and sugar by Ningxia. During the more than 30 years, there were 5 years in which the number of sheep throughout the region reached more than 3 million head. Three of those years were after the Third Plenum. In 1981, the number reached 3.27 million head. Because of the development of agricultural and livestock production and diversification, the people's life has been generally improved. The income of commune members in the Xihaigu region, which had been traditionally poor, also increased generally.

Xinjiang: The whole region's agricultural and livestock production realized bumper harvests for 3 consecutive years, and in 1981 it again realized bumper harvests. The area of planting of food grains decreased by 1.38 million mu, but the total yield still approached that of the previous year. Cotton and oil-bearing crops respectively increased 31 percent and 33 percent over the previous year. The yield of melons, fruits and hops also increased by a large amount. The yield of hops constituted 85 percent of the national production, and the amount exported constituted 95 percent of the national total.

The year-end number of livestock of the whole region increased by about 3 percent over 1980. Because of the development of production, the situation of the poor communes and poor brigades changed. For example, one of the eight poor countries of the whole region is Sule County. The per capita distribution of income of the farm village population of the whole county increased from 54 yuan the previous year to over 80 yuan.

Xizang: In 1981, this region suffered severe drought. Livestock production suffered from damage by snow over large areas. The severity of the disaster in some localities was the greatest in several dozen years. But because of the directives issued by the Chinese Communist Party Central Committee for work in Xizang in 1980, the policy was relaxed and the enthusiasm of the farming and livestock population was mobilized. Agricultural and livestock production of the whole region still realized improved harvests. Diversification developed quickly. It is estimated that the total income and per-capita income throughout the region will both greatly surpass those of the previous year. In the past, the Shannan area asked the state to appropriate 4 million jin of food grains each year, and there were people who had to go elsewhere to make a living. In 1981, this area only had to ask the state to appropriate 400,000 jin of food grains.

Guangxi: Guangxi suffered serious disasters in 1981. The area of sowing of food grain crops decreased by 6 million mu, but the total yield of food grains may still approach the highest level in history. All economic crops realized overall increased yields. The yield of cane sugar is estimated to have increased by 20 percent over the previous year. According to the policy and guidelines to develop and support production in mountain and border regions, the whole region established a group of commercial food grains and economic crop bases as a foundation for further development in the future.

ECONOMIC PLANNING IN AGRICULTURAL PRODUCTION STRESSED

Beijing ZHONGGUO NONGMIN BAO in Chinese 7 Jan 82 p 1

[Article by commentator: "Agricultural Production Must Also Implement Economic Planning"]

[Excerpt] The agricultural economy is an important part of the national economy. The development of the agricultural economy cannot be separated from the overall construction of socialist modernization. Because agricultural development is not isolated, it cannot be separated from the development of industry, communications, science, education and health. Because overall development of agriculture is the foundation for a steady development of the national economy, it must serve the whole body of economic construction. Agriculture must never be separated from the guidance of national planning.

Today, our party has corrected the past mistaken "leftist" tendencies of overly tight control and overcentralization. The situation is becoming better as the broad numbers of farm villages have implemented many forms of production responsibility system centered around linking production to remuneration and contracting work. Does this allow agricultural production to rely entirely on market regulation and to develop freely without national planning? Certainly not. The "Resolution on Certain Questions in the History of Our Party Since the Founding of the Nation" passed by the Sixth Plenum of the Chinese Communist Party pointed out: "We must implement economic planning on the foundation of the public ownership system and at the same time develop the auxiliary function of market regulation." Regardless of what form of production responsibility system is implemented, the agricultural economy still requires economic planning; economic planning must still be the main effort and market regulation must be secondary. Some people think that after implementation of the production responsibility system, the agricultural economy does not need to emphasize economic planning. This is very wrong. Some people even regard the production responsibility system as "dividing the farmland for individuals to work on", and consider that the farmers' production can be completely regulated by the market. This is an even more serious mistake. During the previous period, some new situations emerged in some localities after bumper harvests in agriculture were realized. For example, agricultural sideline products and local specialty products accumulated. Sales were stagnant. Farmers had difficulty selling edible oil, cotton, codonopsis pilosula, prickly ash, and even surplus food grains. But in other localities, because the arrangement of production was not appropriate, production of live hogs dropped; in some cities, there were shortages in the supply of vegetables and procurement of third category agricultural and sideline products dropped. This shows that the overall development of agriculture cannot be separated from the entire plan of building the nation. If the agricultural economy is separated from the national economic construction plan, the proportional development of the national economy will not only become imbalanced, but there will be shortages in the market. Also, blind development in production will cause accumulation of staple agricultural and sideline products, thus hindering the further development of agriculture, slowing the pace of development of agriculture, and bringing economic loss to farmers.

The principles and policies established since the Third Plenum must be firmly implemented. The production responsibility system must be continued. The principle of "never relaxing food grain production, actively developing diversification" is unshakable, because only in this way can the nation and the people become rich. When implementing these principles and policies, we must first think of the nation, and they must be carried out under the guidance of national plans. In recent years, each locality has expanded the production of such economic crops as cotton, oil-bearing crops, flue-cured tobacco, prickly ash and codonopsis pilosula during readjustment of the distribution of production. In developing the light and textile industries, edible oil became basically self-sufficient and the efforts served a good function. But now the situation has changed. Regions of centralized production of some economic crops must pay attention to the new arrangement of national plans. Development of commercial products for which the domestic and foreign markets are already saturated should be discontinued. Even though the market needs some agricultural and sideline products and even though the production of commune member family sidelines is scattered, everyone must consider the national plans, and such production cannot be blindly developed. In general, the departments in charge of agriculture in each locality and the broad numbers of cadres in farm villages must view the whole situation, give careful guidance, and keep in mind the national benefit at all times. The masses of commune members must also consider the whole situation, recognize the whole situation, and actively complete the various national tasks so that our nation's agriculture can realize overall development under the prerequisite of insuring the needs of the nation.

DEVELOPMENT OF QUALIFIED AGRICULTURAL PERSONNEL URGED

Beijing ZHONGGUO NONGMIN BAO in Chinese 10 Jan 82 p 1

[Article by staff commentator: "Pay Attention To Developing Qualified People in Farm Villages"]

[Text] "When there are qualified people, business will be prosperous." Since the Third Plenum of the party, our nation's agriculture has been able to develop relatively quickly on an overall basis because it has relied on policy and on science. But regardless of whether it relied on policy or on science, the key is still people. The many people with a high socialist awareness, with a rich knowledge of science and practical experience, provide forceful assurance of the development of agriculture and other business in our nation.

This year, the agricultural front should do its work better and make greater contributions to the nation. To enable our nation's agricultural development to develop more rapidly, to enable agriculture, forestry, livestock production, sideline production and fishery to develop on an overall basis, more intelligent, technically skilled and talented people are needed, more self-taught scholars, self-taught experts and various types of skilled professionals are needed. Discovering these talented people and utilizing their wisdom are an important task to hasten the development of agriculture at present and a major factor for vigorously developing agriculture.

Our nation's farm villages not only have rich natural resources, but the potential of skilled people and talent is also great. Among them there are: traditional technical talent; new generations of self-taught talent; intellectual youths who have come from the farm villages and returned to the farm villages; old workers who have retired from the factories, mines and enterprises in the cities and towns and returned to the farm village; demobilized personnel who have changed their career to become technicians; temporary workers and contract workers who have participated in national construction projects; civilian technicians who move from one locality to another, etc. In general, there are many kinds of talented people whose skills have not been utilized well for various reasons in the past.

In selecting and using farm village talent, there are still a lot of hindrances. Many people still do not pay enough attention ideologically to this problem. Some people are influenced by the traditional concept of small-scale production. They do not see the urgent need for various types of specialized technical personnel in the overall development of agriculture. Some people mistakenly criticize and limit some traditional technologies as things of feudalism and capitalism; for example, regarding horticulturists and such specialized labor as not engaging in proper work. There are also people who know that a person has knowledge, talent and skill and is willing to contribute to the building of the four modernizations, but for certain so-called political reasons, they are afraid of making mistakes and do not dare hire him. In implementing policy there are also problems. Some people are afraid some commune members will make headway economically and will widen the gap between rich and poor, and they are worried about "polarized division", so they impose many limitations on contracting work to professionals, contracting technical work, giving rewards to surplus production, etc. Some demand perfection. Some insist on seniority and discriminate against the younger generation, and some utilize their authority to place personal friends or relatives; thus people with specific talent, skills and knowledge cannot be correctly employed.

Today, the time has come when these problems must be solved. Party organizations and cadres at each level in farm villages must include in their daily agenda the problem of discovering and employing various types of specialized talent. They should care about and pay attention to such talent so that such people can contribute all their wisdom and talent to building a rich and prosperous new farm village.

CONFERENCE DISCUSSES DEVELOPMENT OF AQUATIC PRODUCTS

Beijing GUANGMING RIBAO in Chinese 13 Jan 82 p 2

[Report by reporter Lu Liang [4151 5328]: "Develop Sea Water Culture, Exert Efforts To Increase Aquatic Products; a Group of Experts Enthusiastically Discussed the Direction of Development of Sea Water Cultivation of Fish"]

[Text] A group of experts and professors attending the national conference held recently in Hangzhou to discuss the direction and key points of developing sea water fish cultivation pointed out that our nation's ocean fishery production will not increase very much in the near term because of overly intensive fishing activities. In this situation, developing sea water fish cultivation has become the main way to increase marine production.

Experts believe that our nation's sea water fish cultivation has a great potential. The whole nation still has over 90 percent of shallow seas and beaches which can be used for cultiviation. There are nearly 100 different varieties of marine life which can be cultivated along our nation's coastal regions. In selecting the varieties for cultivation, we should suit measures to local circumstances, develop many varieties, and not exercise arbitrary uniformity. Within the national territory, we should first strengthen and redevelop high-yielding staple varieties with a large economic value, such as kelp, laver, oysters, razor clams, mussels, and prawns. Regarding other varieties such as clams and blood clams, which also have a definite yield, there is a traditional custom of raising such marine products and rich experience. If each locality emphasizes strengthening and developing such efforts, they will serve importantly to solve the needs of the people and the masses for marine products.

At the same time, in specific regions, the study of some local varieties such as mullet, barracuda, zhe mu yu, luo fei yu, clams, pearl shells, abalone, scallops, gracilaria confervoides, agar, and ulopteryx pinnatifida should be strengthened and their cultivation should be actively supported and developed. In this way, the marine products which can be supplied to the market will gradually increase.

Experts have pointed out that the propagation of marine resources must also be emphasized. On the one hand, we must establish protective zones and protective seasons, actively and effectively protect and propagate presently available fish, shrimps and shellfish and such important resources, and prohibit indiscriminate catching and fishing. On the other hand, we must select some herbivorous and omnivorous fish and shellfish for artificial incubation and later release them into ocean regions suitable for their growth so that they can grow naturally in the ocean for catching later. At present, the ocean region for propagation should begin in Bohai to gradually establish an ideal ecological system for comprehensive development of mainly prawns along with fish, shrimps, shellfish and algae.

The conference was sponsored by the special committee on sea water cultivation of the China Aquatic Products Society.

AGRICULTURAL, SIDELINE PROCUREMENT PLANS FOR 1981 OVERFULFILLED

Beijing ZHONGGUO CAI MAO BAO in Chinese 14 Jan 82 p 1

[Article: "Last Year, Procurement Plans for Agricultural and Sideline Products Were Completed With Surplus; the Total Value Reached More Than 23.5 Billion Yuan, an Increase of 7 Percent Over the Previous Year; the Amount of Cotton, Tobacco, Bast Fibers, Tea and Raw Lacquer All Increased Notably Over the Previous Year"]

[Text] It has been learned from the National General Supply and Marketing Cooperative that in 1981, the nation's procurement plans for agricultural and sideline products were completed with surplus. As of 31 December last year, a total of 23.54 billion yuan worth of goods was procured, completing the whole year's procurement plans with a surplus of 7 percent and registering an increase of 7 percent over the total amount procured in 1980.

The amount of some major staple agricultural and sideline products procured increased in varying degrees. Over 52.43 million dan of cotton were procured, an increase of 8.4 percent over the previous year. Over 23.19 million dan of flue-cured tobacco were procured, an increase of 88 percent over the previous year. Over 10 million dan of round pot jute and bluish dogbane were procured, an increase of 13 percent over the previous year. Over 5.4 million dan of tea were procured, an increase of 8.2 percent over the previous year. More than 300 million jin of wool were procured, an increase of 3.1 percent over the previous year. Over 16 million sheepskins were procured, an increase of 26.2 percent over the previous year. More than 330,000 dan of palm were procured, an increase of 5.6 percent over the previous year. Some 54,000 dan of lacquer was procured, an increase of 12.5 percent over the previous year. Because market management in some regions did a poor job of handling shortages of some agricultural and sideline products, many purchasers rushed to buy up the inventories, and the procurement plans were not completed well. For example, only some 3.38 million cowhides were procured during the whole year, a drop of 19.1 percent from the previous year. The amount of procurement of some third category indigenous and sideline products also decreased on a large scale.

The regional statistics showed that 22 provinces, cities and autonomous regions, including Guizhou, Yunnan, Xinjiang, Liaoning. Jilin, Kiangsu, and Shandong, completed the annual procurement plans with surplus. Among them, 15 provinces, cities and autonomous regions registered increases of varying degrees over the actual amounts procured during the previous year. There were also some provinces, cities and autonomous regions, such as Shaanxi and Gansu, which suffered from severe natural disasters and could not complete the procurement plans, and the amounts procured were less than the actual amounts procured the year before last.

TEST PLANTING OF NEW PADDY RICE VARIETIES REPORTED

Shuang Gui No 1

Guangzhou NANFANG RIBAO in Chinese 20 Nov 81 p 2

[Article by Chen Sisi [7115 2448 2448] of the Guangdong Science and Technology News Agency: "New Superior Variety of Paddy Rice 'Shuang Gui No 1' Which Is Better Than 'Gui Chao No 2'"]

[Text] The "shuang gui No 1" paddy rice variety was originally designated "shuang gui 210". It was a hybrid produced in 1981 from "gui chao No 2" and the dense and fast-growing, late-maturing, late-crop "gui yang ai C17" as the female. It was a new variety of paddy rice successfully bred in 1979 by screening and selecting from the colony of combinations. For 2 years it was test planted at many test localities and in large areas in Guangdong and Guangxi. Such tests showed that "shuang gui No 1" is short stemmed, tolerant to fertilizers, high-yielding, resists lodging, has a relatively strong resistance to bacterial blight of rice and blast of rice, and the quality of its rice is good. Its disease-resistance, resistance to lodging and properties of producing bumper harvests and stable yields are all better than those of "gui chao No 2". Under superior conditions of cultivation and management, its per-mu yield can reach over 1,000 jin.

"Shuang gui No 1" has such species characteristics as strong sensitivity to temperature and weak sensitivity to light. It can be used both for the early and the late crop. Planted as the early crop, its full growth period is about 140 days, maturing 5 days later than "qui chao No 2". When it is sown earlier, its growth period is prolonged, and when it is sown late, its growth period is correspondingly shortened. As the late crop, it manifests early maturation with a full growth period of about 125 days. Sown at the beginning of July and transplanted during the last 10 days of that month, it can achieve full heading from the end of September to the beginning of October, favorable for safely avoiding cold dew winds.

Three New Varieties

Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 12, 17 Dec 81 p 7

[Article: ["Introduction to Paddy Rice Varieties"]

[Text] Guang Wen No 5 and Guang Wen No 10 (intermediate xian)

These two varieties were successfully bred by selective breeding and crossing guang xuan No 3 (Guangxi short stemmed variety) with wen lu No 1 (our province's local tall-stemmed variety) at our academy's Paddy Rice Institute from 1970 to 1975. From 1975 to 1977, they participated in the joint regional experiments of superior varieties of intermediate xian rice of the whole province, and their yields placed first and second at most test localities. In 1976, they began to be test planted at various localities in the province and since their popularization, practice has shown that because these two varieties have traits of the regional varieties of our province, they can better adapt to frequent climatic changes of cold and hot weather. They produce notably increased yields in rice regions at 900 to 1,300 meters above sealevel, whether in one-crop fields, two-crop fields of rice and wheat, or two-crop fields of rice and rape. The per-mu yield in large areas is 800 to 900 jin, with highs reaching above 1,000 jin. In 1978, the Xiazai production team of Huayan Commune in Anshun County planted guang wen No 10 after harvesting 5.89 mu of wheat. The average per-mu yield was 1,235.4 jin. These two varieties are being popularized over large areas in central Guizhou in the counties of Zunyi, Xifeng, Jinsha, Yinxi, Puding, Qingzheng, Xiuwen and Zhijin. In 1980, a total of 200,000 mu was planted.

Characteristics: Both are intermediate in height. The plant height is ordinarily 85 centimeters. When the temperature is high and fertility is sufficient, their height can reach about 95 centimeters. The apicule of the two varieties is colorless and awnless. In the central regions of our province, the full growth period is generally 150 to 160 days for guang wen No 5; guang wen No 10 matures 3 to 4 days earlier. Guang wen No 5 is a large panicle variety. The number of full grains per panicle is generally over 100 grains. The leaves are broad and large. The color is light. The stem is thick, and the tillering strength is relatively weak. The color of the glume is yellow and shiny. The color of the rice grain is pure white. The thousand-grain weight is about 26 grams. Guang wen No 10 is a variety with many panicles. The number of full grains per panicle is 80 to 85 grains. The leaves are narnow and stiff and their color is dark green. The stem is relatively thin. The plant's tillering strength is strong. The color of the empty glume is dark yellow with occasional light black spots. The color of the rice grain is white and slightly dark. The thousand-grain weight is about 25 grams. Its resistance to panicle neck blast of rice disease is relatively poor.

Key points in cultivation: (1) Guang wen No 5 is relatively less tolerant to fertilizers. To avoid overprosperous growth, it is not suitable for planting in highly fertile fields. When planted in such fields, the leaf surface area will become overly large, the canopy will be closed, and the number of empty husks will increase, unfavorable to producing bumper harvests. Guang wen No 10 has narrow and stiff leaves, so cultivating it in fertile fields is favorable for it to develop its potential of producing many panicles and high yields. In the winter fields constantly soaked and infertile fields of yellow mud, additional phosphorous fertilizers should be added to the base manure. (2) The density of seedlings for both should be 6 x 5 cun. In fields with sufficient fertility and when the seedlings are transplanted early, the seedlings can be planted in a density of 7 x 5 cun, with 8 to 9 leaves per hole. The height of the seedlings suitable for transplanting is about 7 cun. Old seedlings that have been overaged should not be transplanted in order to avoid affecting tillering in the large fields. Guang wen No 10 planted in regions affected seriously by blast of rice should be fertilized to stimulate stable and healthy growth. Overapplication of nitrogen fertilizers during the latter period of growth should be avoided.

The price of each jin of seeds is 0.14 yuan, or 0.7 jin of food grains in ration ticket. The amount of seeds supplied is not limited. Packaging and mailing costs are charged according to actual cost.

Lu Beifan [4151 1014 0416] of the Guizhou Provincial Agricultural Science Academy

Yin Yu 272 (intermediate xian)

Intermediate xian rice variety yin yu 272 is a variety of many panicles successfully bred from the natural hybrid plant of zhen zhu ai in 1973 at our institute. In 1977, it participated in regional tests in the province. In 1978 it participated in the regional tests of the southern rice regions. The per-mu yields surpassed 1,000 jin, ranking among first place. It produced 10 to 15 percent more in yield than zhen zhu ai. Over the past several years, the results of various regional experiments, test planting and large area popularization in Guizhou Province showed that the per-mu yield was generally 800 to 900 jin, with highs reaching over 1,000 jin. The area of planting in 1980 was about 20,000 mu. At present, it is mainly being popularized in the northeastern regions of Guizhou.

Characteristics: The full growth period is about 135 days. The plant is about 100 centimeters tall. The plant type is appropriately clustered and loose. The leaves are narrow, long and uplifted. The average width between the boot leaf and the first leaf below it is slightly less than that of zhen zhu ai. The leaf at the central position is slightly longer. The length of the panicle is intermediate. The number of full grains per panicle is 80 to 90 grains. The fruiting percentage is higher than that of zhen zhu ai. The color of the grain is yellow. The apicule is colorless and has an occasional short awn. The quality of rice is intermediate. The percentage of yield of rice is 75 percent. The thousand-grain weight is low, 24.5 to 25.5 grams. Its tolerance to aridity is relatively strong, but its stems are soft and lodge easily. The panicle is small and has few grains. The grains are sparse.

Key points in cultivation: It is suitable for cultivation in fields of medium and high fertility. Its seedling age is about 30 days. Its planting density is 6 x 5 cun and 7 x 5 cun in fertile fields, with 6 to 8 leaves per hold.

The price of seeds is the same as that for guang wen No 5.

REVERSAL OF DECLINE IN PIG PRODUCTION EMPHASIZED

Beijing ZHONGGUO NONGMIN BAO in Chinese 3 Jan 82 p 1

[Article: "Production of Live Hogs Cannot Be Relaxed"]

[Text] According to reports by concerned departments, at the end of 1981, the number of hogs in pens and the number of hogs marketed have both decreased. Each locality should pay due attention to this and not disregard it.

There are many reasons for the decrease in live hog production. The main reasons are that the leadership did not pay sufficient attention to the new problems and the new situation that have emerged along with the good situation in the farm villages, and they did not study and solve problems related to some of the policies to encourage the masses to raise hogs, market management, and disease prevention and vaccinations. Now, when the problems are beginning to be exposed, we should be decisive, implement countermeasures in time, and conscientiously solve the problems.

Some localities have already taken concrete measures to handle the drop in production of live hogs; for example, implementing assigned procurement and contracting production of food grains, oil-bearing crops, livestock and eggs to families; assuring the supply of feed for families raising hogs; zoning feed plots; subsidizing feed grains; and rewarding commune members who have completed the tasks of assigned procurement of live hogs and selling more hogs, giving rewards of industrial products that are selling well, etc. The situation in each locality is different and measures should be suited to local circumstances; corresponding measures should be taken to conscientiously implement policies, encourage commune members to raise more and sell more, and to solve actual problems, including the production of feed, disease prevention, improving varieties, and establishing production bases for commercial hogs.

In general, developing hog raising is an important matter that affects improvement of the people's life, stabilizing the markets in the cities and villages and stabilizing commodity prices; it is an important measure that helps to develop diversification, improve the agricultural structure, promote industrial and agricultural production, and increase the income of the masses. Each locality must investigate and study, summarize experience, concretely carry out this work and rapidly change the decline in the production of live hogs.

COMMUNE, BRIGADE ENTERPRISE TOTAL 1981 INCOME REPORTED

Guangzhou NANFANG RIBAO in Chinese 6 Jan 82 p 1

[Article: "Our Province's Commune and Brigade Enterprises Continue To Progress in Readjustment; Last Year Total Income Reached Over 4.9 Billion Yuan, an Increase of Nearly 20 Percent"]

[Text] In 1981, our province's commune and brigade enterprises again realized new progress in readjustment. According to forecasts by each locality, the total income of the commune and brigade enterprises throughout the province may reach over 4.96 billion yuan, an increase of more than 800 million yuan over the previous year, or an increase of 19 percent. On the basis of preliminary estimates, the counties and cities with a total income of over 100 million yuan are Shunde, Nanhai, Dongwan, Zhongshan, Fanyu, Xinhui, Chaoyang, Chaoan, Xieyang, Huaxian, Taishan, Kaiping County and the suburbs of Guangzhou, and Foshan city, an increase from last year's 12 counties and cities to 14 counties and cities.

Our province's commune and brigade enterprises continued to progress in readjustment, as characterized by the following:

1. The commune and brigade enterprises were further readjusted. Their distribution gradually became more rational. The products were more suited to the market. Products which were urgently needed by the people and masses in production and living, such as building materials, household electrical appliances, clothing, shoes and hats, furniture and small hardware and small plastic commercial products all increased greatly. The production of medium and small farm tools also changed for the better.

2. Joint enterprises and production brigade enterprises continued to develop.

3. A new way to open up the channels of supply and marketing was created with the establishment of various types of specialized companies, implementation of specialized management, and integration of production, supply and marketing so that production by commune and brigade enterprises gradually developed toward specialization. In addition, foreign trade of commune and brigade enterprises also underwent new development. In 1981, the production value of export products by commune industries in Guangzhou city increased by more than 50 percent over the same period of the previous year.

DONGFANG COUNTY ACHIEVES BUMPER HARVEST IN 1981

Guangzhou NANFANG RIBAO in Chinese 1 Jan 82 p 1

[Article: "Dongfang Shines With a Brighter Glow; Last Year Dongfang County Realized an Overall Bumper Harvest of Food Grains, Oil-Bearing Crops and Sugarcane, and Income of Commune Members Increased"]

[Text] After Dongfang County implemented the production responsibility system of contracting work to families on a popular basis, it realized an overall bumper harvest in agricultural production in 1981. The highest records in history were created in food grain production, production of oil-bearing crops, sugarcane production, watermelon seed production and livestock production. The income of commune members increased on a large scale. Dongfang County, which was a poor county for a long time, is now shining with even brighter splendor.

According to statistics, in 1981 the whole county's total production of food grains reached 102 million jin, an increase of 32 percent over 1980. In 1980, the whole county consumed 15.7 million jin of returned food grains. Up to the end of December 1981, the whole county consumed only 340,000 jin of returned food grains, while the amount of food grains submitted and sold to the state by farmers reached 12.36 million jin.

Diversification in this county also developed on a relatively large scale. In 1981, the total yield of peanuts in the whole county reached 4.45 million jin, an increase of 42 percent over the previous year. The more than 26,000 mu of sugarcane produced a total yield of 40,000 tons, an increase of more than fourfold over the previous year. Watermelon seeds, the traditional crop, increased 43 percent. The number of cattle on ranches and hogs in pens increased by more than 10 percent over the previous year. Cattle increased by 7,320 head, an increase of 14.5 percent. The 3,900 mu of rubber already planted are growing well. In 1981, the per capita average income increased from 37 yuan the previous year to 86 yuan, an increase of more than onefold. Annual average rations of food grains for commune members increased 120 jin over the previous year. Up to the end of October, savings of commune members in farm villages throughout the county reached 2.275 million yuan, an increase of 813,000 yuan over the same period the previous year.

BRIEFS

EDIBLE OIL PROCUREMENT--This year, our province's peanuts realized a relatively large-scale increase in yield. Procurement of edible oil for the state also notably increased over that of the same period last year. According to statistics, up to 15 December, the whole province procured a total of over 106 million jin of edible oil, storing 5.4 million jin more in warehouses than in the same period last year and completing the annual procurement plan with a 30-percent surplus. This year, because each locality readjusted the distribution of production and expanded the planting area of peanuts, and because the national procurement policy was stable, the enthusiasm of the farmers for planting peanuts was greatly mobilized and relatively large-scale increases in yield were realized. Farmers in the peanut-producing regions all demonstrated their patriotic spirit, their love for the collective and for socialism, and submitted more edible oil for sale to the state. For example, Shantou and Zhanjiang, which are the two major edible oil producing regions, respectively submitted 11 million jin and over 2.9 million jin more edible oil to the state than in the same period last year. LIVESTOCK PRODUCTION UP IN FLATLANDS DESPITE DROUGHT

Shijiazhuang HEBEI RIBAO in Chinese 29 Dec 81 p 1

Large Domestic Animals in the Grassland Area of Zhangjiakou Prefecture

[Article by Hu Yuquan [5170 3768 3123], Jin Hongyu [6855 7703 6657], Ma Yunshan [7456 0061 1472], and Li Shibin [2621 0013 2430]: "Break Through the Confines of the 'Leftist' Ideology, Actively Implement the Production Responsibility System in Livestock Production; Zhangjiakou Prefecture Raises Fat and Healthy Livestock on Flatlands"]

[Text] The leadership at each level of administration of the flatlands in Zhangjiakou Prefecture has broken through the confines of the "leftist" ideology, and has implemented and perfected the production responsibility system of establishing prices for families to purchase livestock and for families to raise and use large domestic livestock in a big way. The growth and fattening of livestock have been generally good, even though the area has suffered severe drought for 2 consecutive years. Over 226,000 head of large livestock on the flatland have already been herded into sheds for feeding for over a month, and the fattening is above 80 percent. The number of sheep has increased to over 814,000 head, surpassing the highest level in history by 10.5 percent. The percentage of large livestock and sheep marketed, the percentage of meat production and the percentage of commercial commodities have all increased over last year.

This year, as the spirit of the Sixth Plenum and the "decision" are passed on and implemented, the Zhangjiakou Prefecture CCP Committee held classes to discuss the standards for truth. The broad ranks of cadres and masses on the flatlands conscientiously reviewed and summarized the experience and lessons in cultivating and managing livestock since the start of the cooperative movement. The wishes of the masses were carried out and the following forms of production responsibility system in raising livestock were implemented: Prices were established for families to raise and use livestock. Each brigade had families raising livestock, and profits from newborn livestock were shared. The female livestock brigades had families raising livestock; the costs were guaranteed, while profits from newborn livestock were shared. These livestock converted into money for the families constituted over 90 percent of the total number belonging to the production teams, fully mobilizing the enthusiasm of the masses to protect and care for the animals.

Mandetang Commune in Kangbao County had a total of 3,047 head of large livestock. Last year, the whole commune suffered from severe drought. This spring, the livestock raised by the collective were thin; so after democratic discussion among the commune members, they were all converted to money for the families. The commune members built cowsheds and added night-time grass as feed. Everyone was concerned. Every family took care of the livestock carefully. The livestock was quickly fattened. Although this year the area again encountered severe drought and although only 50 percent of the annual harvest was achieved in agriculture, the number of livestock did not decrease but increased by 412 head over the number before the livestock was assigned to the families for feeding. Dasuji Commune in Shangyi County this year realized only 30 percent of the annual harvest. It is estimated that if the livestock had been fed by the collective, there would have been a shortage of 6.6 million jin of grazing grass and a shortage of 660,000 jin of feed. The two combined would have required capital of 192,000 yuan. Because the livestock was distributed to the families for raising, commune members began storing grass and protecting the livestock when autumn arrived, and the feed and grass were basically self-sufficient.

The development of livestock has increased the income of commune members. Up to the end of November, the four counties on the flatlands had already sold over 30,700 head of large livestock and over 109,000 head of mutton sheep, and there were also large numbers of other livestock products.

HUOLU COUNTY AGRICULTURAL, LIVESTOCK, SIDELINE PRODUCTION UP

Shijiazhuang HEBEI RIBAO in Chinese 29 Dec 81 p 1

[Article by Li Laiping [2621 0171 1627], and Zhang Wenguang [1728 2429 0342]: "Agriculture, Forestry, Livestock Production, Sideline Production All Developed; Income Doubled in 3 Years."]

[Text] Agriculture, forestry, livestock production and sideline production have undergone overall development in Huolu County.

The total agricultural income of the whole county reached over 85 million yuan, an increase of 32.35 million yuan over that before the Third Plenum. The per capita distributed income increased from 89 yuan 3 years ago to 172 yuan, and per capita income from family sidelines was above 50 yuan, so the actual standard of living reached over 220 yuan.

Huolu Country is one-third mountainous, one-third hilly and one-third flatland. It neighbors Shijiazhuang city. It has a foundation for developing agriculture and superior conditions for developing industries and sidelines. After the Third Plenum, the county criticized leftist tendencies, liberated ideology, started out from the actual situation, readjusted agricultural distribution, and sped up the development of agriculture.

First, in agriculture, the county stabilized the production of food grains, promoted cotton production and reduced the cost of agriculture. In food grains production, the county strictly controlled the number of mu planted, increased the per-mu yield, preserved the total yield, and at the same time, transferred cotton appropriately to good land suitable for planting cotton, conscientiously implemented the fixed number of mu, changed false reporting of more while planting less, and prevented interplanting of food grains to squeeze out cotton. This actually expanded the planting area of cotton. In this way, food gain production of the whole county increased from a per-mu yield of over 850 jin before the Third Plenum to 1,000 jin, an average annual increase of 50 jin. This year, although disasters reduced the yield, it was still above 70 jin. Increases in food grains and in cotton were realized. At the same time, the county actively implemented the responsibility system of linking production to remuneration and conserved labor and capital, thus reducing the annual agricultural expenditure by over 2 million yuan. Public accumulation of capital increased by 1.43 million yuan over the previous year, and distribution to commune members increased by 3.34 million yuan, a per-capita increase of 12 yuan.

Second, the county increased building materials, promoted transportation, and developed industry and sideline production in a big way. It organized the communes and brigades to establish production of building materials and transportation services as sidelines. Those who could fire bricks were told to build kilns; those who could quarry were told to build rock quarries to satisfy the construction needs in Shijiazhuang city. At present, over 270 brick kilns, lime kilns, rock quarries and quartz mines have been established. Nearly 10,000 persons have been employed. The net income from sideline production of building materials has reached 6.7 million yuan. Led by the sideline production of building materials, industrial sidelines of casting steel, casting iron, repairs, noodle manufacturing, foodstuffs manufacturing, paper manufacturing, and construction have also developed. The whole county already has over 1,780 such operations employing over 19,000 people.

Third, the county managed forests and fruit production, and actively assisted families in cultivation. Among the whole county's 203 brigades, 192 have established fruit gardens covering a total of 10,000 mu. Annual income from fresh fruits reached 6.21 million jin. In developing livestock production, the county committee actively encouraged and assisted key livestock raising families and specializing families. At present, the whole county has 1,132 key livestock raising families. Led by them, over 95 percent of the total number of farm families throughout the county have engaged in family livestock raising. The per-capita income from family livestock cultivation has reached over 50 yuan.

ALL-ROUND CAPITAL CONSTRUCTION ON FARMLAND REPORTED

Wuhan HUBEI RIBAO in Chinese 28 Dec 81 p 1

[Article by Cheng Qijing [4453 0796 4544]: "Insist on the Principle of Whoever Benefits Should Take the Responsibility, Mobilize the Enthusiasm of the Masses; Capital Construction for Water Conservancy on Farmland Throughout the Province Is Launched on an Overall Basis"]

[Text] Capital construction for water conservancy on winter farmland throughout the province has been launched on an overall basis. At present, over 890,000 laborers have joined in the work, including over 96,000 people working on key water conservancy projects.

In September of this year, after the provincial people's government held the provincial farmland capital construction conference, the localities and cities held special conferences one after the other to reiterate the goals of the provincial conference and implement the measures decided upon by the provincial conference. The local and city conferences also combined the tasks with the actual situation of the locality and appropriately arranged the tasks for this winter and next spring. Full preparations were carried out regarding ideological and organizational leadership, labor and machinery. After capital construction for water conservancy on farmland was launched on an overall basis, each locality strengthened construction management, implemented the system of professional contracts, established tasks, determined investment, established quality standards and set the time for completion. After construction of the Huohe reservoir in Xunyang Prefecture was contracted by the provincial water conservancy construction corps, construction progressed quickly. The quality of construction also notably improved. All localities with favorable conditions have implemented mechanized construction. Xianning Prefecture has a concentration of 47 large and medium machinery units. Mechanized construction was used in fortifying the Wangying reservoir, in the capital construction of several key places of the Siyi public embankment, and the Chibi dry embankment, and in carrying out annual repairs. Over 2,000 square meters of earth were moved to the construction sites every day. This lessened the labor intensity of commune members and also hastened the progress of construction. The machinery was welcomed by the masses.

At present, engineering command headquarters have been established for over 70 construction projects throughout the province. Construction of some projects has already entered the final stage. The construction project of the canal system of the Sangan canal in the Yingdan irrigated region in Xiangyang Prefecture has had a work force of over 17,000 people since November. Xiaogan Prefecture has organized 100,000 laborers to dredge and repair large and medium reservoirs, pumping stations and canals through concentrated effort. Work on certain segments of the canal has been completed. Small water conservancy facilities have mushroomed everywhere. Each locality has insisted on the principle of whoever benefits should be responsible. The labor force that works in ordinary years has been divided and assigned to the construction teams according to the number of laborers needed, including families and individuals, thus mobilizing the enthusiasm of the masses.

Juiji Commune in Nanzhang County began construction at 417 localities this year. It planned to employ 8,000 laborers, but the labor force actually reached over 9,400 persons, and some of the construction projects have already been completed. Each locality has decided to seize the opportune time of winter to complete major construction tasks in one vigorous effort before the spring holidays and to strive for taking the initiative to realize benefits this year and to achieve agricultural bumper harvests next year.

INDUSTRIAL PRODUCTION OF COTTON BOLLWORM VIRUS STARTED

Wuhan HUBEI RIBAO in Chinese 29 Dec 81 p 1

[Article by Zhang Liang [1728 5328]: "Another New Weapon to Prevent and Control the Cotton Bollworm; Our Nation's Pioneer Effort in Developing the Cotton Bollworm Virus Has Led To the Start of Industrial Production"]

[Text] After 9 years of difficult exploration, industrial production has begun of the cotton bollworm virus developed jointly by the Microbiology Research Institute of the Jingzhou Prefecture, the Insect Virus Research Laboratory of the Biology Department of Huazhong Normal College and the Institute of Automation Applications and Technology in Changsha city. Now there is hope of mass-producing this new pesticide pioneered in our nation to supply the cotton areas.

The cotton bollworm is one of the major pests that causes the most severe damage in cotton production. In the past, highly poisonous pesticides were mainly used to spray the plants. As the resistance of the cotton bollworm became stronger, the effect of control and prevention became weaker; thus, large-scale reduction in the yield of cotton has occurred and people and animals have been endangered. Since 1973, the Microbiology Research Institute of Jingzhou Prefecture and the Insect Virus Research Laboratory of the Biology Department of Huazhong Normal College have cooperated and searched for new methods of biological prevention and control of cotton bollworms. They found a strain of "heliothis nucleopolyhedrosis virus" in the dead bodies of cotton bollworms that had died naturally. This type of virus is strongly infectious. When healthy insects are infected, they quickly become ill and die. During the past several years, experiments have been conducted in 17 provinces and cities throughout the nation and they have proven that the percentage of control and prevention of this kind of viral pesticide is above 85 percent, it is not harmful to humans or animals and it does not pollute the environment.

To enable mass production of this type of virus so that it can be used in large field production early, scientific and technical workers developed a whole set of machinery equipment for year-round cultivation and propagation of cotton bollworms, for infecting them with the virus, and for making the dead insects into pesticide. During the last 10 days of December, experts and professors who joined together to evaluate the product reached the conclusion that the study of the cotton bollworm virus and its industrial production have opened up a new path for preventing and controlling insect pests of cotton in our nation. They also suggested that experimental demonstration be expanded and its application be actively popularized.

BRIEFS

PINE MOTH CONTROL--Anlu County has used bai jiang (4101 0304) bacteria and Wuhan bacillus and such microbial pesticides to treat the pure masson pine forest of 280,000 mu and has consistently controlled the emergence of and damage by pine moths for 8 years. Anlu County is in a hilly region and is an area where pine moths occur frequently. Because the county insisted on prevention year after year and because it alternately used various microbial pesticides, the area of occurrence of pine moths has been reduced from 80,000 mu in 1974 to 100 mu in 1981. The percentage of trees affected by the pine moth has been contained to below 5 percent. The density of the population of pine moths has also dropped from 66.4 moths per tree in 1974 to 0.1 moth. [Text] [Wuhan HUBEI RIBAO in Chinese 26 Dec 81 p 2] 9296

PEANUT NODULE BACTERIA--The Jingzhou Prefecture Microbiology Research Institute has screened and selected a superior quality peanut nodule bacterium. After 2 years of seed dressing experiments, an experimental demonstration in large fields covering 1,100 mu was conducted at a dozen test locations throughout the prefecture this year. Peanut plants planted from seeds dressed with this nodule bacterium grew prosperously, the leaves were green, the plants had many nodules, the nitrogen fixing ability was strong and the yield of peanuts was high. According to statistics, the yield of the demonstration fields increased by more than 20 percent over the control area. The 3 mu of experimental fields of the Jianghu farm in Tianmen County produced an average per mu yield of 1,100 jin of fresh peanuts, an increase of 34 percent over the control area. The science committee of the prefecture is preparing to popularize this new agricultural technique in a big way throughout the prefecture next year. [Text] [Wuhan HUBEI RIBAO in Chinese 26 Dec 81 p 2] 9296

REGENERATIVE RICE VARIETY--This year, Pugi County introduced the new variety of regenerative rice "yan xian 203" introduced by the Hunan Provincial Agricultural Sciences Academy and test planted it in the hilly regions, in plains, and on the banks of lakes successfully. According to statistics of six test points, the average per-mu yield of the first crop was 305 jin 5 liang. The general characteristic of regenerative rice is that it only needs to be sown once. Its seedlings need to be cultivated only once and they need to be transplanted only once. This can conserve the amount of seeds and labor for a crop. Because the regenerative ability of "yan xian 203" is strong, the total average yield of the two crops is higher than the yield of the local early and late continuous crops. In double cropping rice regions, it is a new variety with great potential. [Text] [Wuhan HUBEI RIBAO in Chinese 26 Dec 81 p 2] 9296

AGRICULTURAL WEATHER OBSERVATION POINTS--The provincial Metrological Science Research Institute and the Wuhan Hongshan Ward Vegetable Bureau have established two special agrometeorological observation points in Hongshan Ward. One is set up at the vegetable experiment station of Hongshan Commune mainly to observe the climatic conditions required for growing beetroots. The other is set up at the vegetable experiment station of Fenghuo Brigade of Qingling Commune mainly to observe the climatic conditions needed for planting and growing lotus roots. The establishment of these two stations will provide meteorological data to improve the planting method of vegetables, to improve the quality of vegetables and to reduce production costs. LIAONING

BUMPER HARVESTS ACHIEVED IN 1981 DESPITE FLOODS, DROUGHT

Shenyang LIAONING RIBAO in Chinese 17 Dec 81 p 1

[Article: "The Production Responsibility System Mobilized the Productive Enthusiasm of the Farmers; the Value of This Year's Total Production in Our Province and the Income of Commune Members Will Surpass Last Year's; the Average Per Capita Income of Commune Members Received From the Collective and From Family Sidelines May Reach 200 Yuan"]

[Text] Some regions of Liaoning Province suffered major floods and some experienced drought this year, but agricultural production still realized bumper harvests. The total value of agricultural production and the average per capita income of commune members will both surpass those of last year, which was a bumper harvest year.

Major drought has continued for 2 years in Chaoyang Prefecture in western Liaoning and in parts of Jinzhou city and Fuxin city. Some communes in Dalian city and Yingkou Prefecture in southern Liaoning suffered a major flood. the area of damage covered more than 15 million mu, and the disaster area covered 11 million mu, of which 5 million mu produced no harvest. But because the various forms of agricultural production responsibility system were established and made sound by suiting measures to local circumstances this year, the productive enthusiasm of the farmers was mobilized. The agricultural structure was further readjusted. Diversification was actively developed. The standard of scientific planting was elevated with effort. Most regions realized increased yeilds and increased harvests. According to preliminary statistics compiled by concerned departments, this year the total yield of food grains throughout the province may still surpass last year, which was a year of bumper harvests. The total yield of economic crops, except for tussah silkworm cocoons and sunflowers was generally higher than last year's level. Of this total, the yield of cotton throughout the province increased 5.4 percent over last year. The yield of peanuts increased 17.1 percent. The yield of sesame increased 42 percent. The yield of sugarbeets increased 72.4 percent, and the yields of flue-cured tobacco, fruits and vegetables all surpassed those of last year. There were also new developments in forestry, livestock production, sideline production and fishery. This year, income from family sidelines of commune members throughout the province increased by one-third over last year. This yeas has been the best year in history. According to preliminary estimates, this year the average per capita income received by commune members throughout the province from the collective will reach over 126 yuan. Adding this to the income from family sidelines, the actual average per capita income may reach 200 yuan.

At present, the broad masses of commune members in the farm villages throughout the province are enthusiastically submitting and selling new food grains and local specialty products to the state and they are actively carrying out winter production activities to prepare for next year's production.

CHANGTU COUNTY LEADS PROVINCE IN FOOD GRAIN PRODUCTION

Shenyang LIAONING RIBAO in Chinese 21 Dec 81 p 1

[Article: "Changtu County's Broad Masses of Commune Members Make New Contributions to the Nation Again This Year; the Total Yield of Food Grains, the Amount of Commercial Commodities Submitted and Sold to the State, the Percentage of Commercial Food Grains, and the Per Capita Average Amount of Food Grains Submitted and Sold to the State All Lead the Province"]

[Text] This year, the broad masses of commune members in the farm villages of Changtu County again made new contributions to the nation. The total yield of food grains of the community, the amount and percentage of commercial products and the per capita average of commercial food grains produced all led the whole province.

Up to 17 December, the total yield of food grains throughout the country reached 1.9 billion jin, and 1.05 billion jin were submitted and sold as commercial food grains. The percentage of commercial food grains reached 60.7 percent. Each person provided 1,270 jin of commercial food grains. All of these surpassed the past levels of the county and all ranked first in the whole province. The total yield of food grains in society increased by 810 million jin over that in 1977, prior to the Third Plenum, and the amount of commercial food grains increased by more than 570 million jin. Compared to 1980, a year of large bumper harvests, the total yield of food grains in society increased 330 million jin, and commercial food grains increased by more than 250 million jin. The per capita production of commercial food grains increased by 303 jin, or an increase of 10 percent.

Every brigade of the 37 communes of the whole county increased the yield and the harvests. They did not forget about the nation during the bumper harvests. The amount of commercial food grains submitted and sold to the state not only surpassed 1.7 billion jin, but the quality was also good. The moisture content was low, and many varieties of crops were involved. The whole province produced over 130 jin of soybeans and submitted and sold to the state more than 83 million jin. The first-grade food grains submitted and sold to the state by the whole county constituted 75 percent. Among them, first-grade corn constituted 80 percent, and first-grade soybeans and sorghum constituted over 70 percent. The first-grade product of the 50 million jin of corn submitted and sold to the state by Baoli Commune constituted 98 percent. The water content in food grains dropped by a large amount. The water content in corn averaged 21 Q1 [0003], a drop of three shuifen [3055 0433] from last year. This year's food grain procurement work was emphasized by the county committee and the county government. The food grain departments and the communes and brigades cooperated closely. The power, public secutiry, railroad and transportation departments all cooperated, and compared to last year, procurement was 1 month ahead of schedule.

BRIEFS

KAIYUAN COUNTY SOYBEAN PRODUCTION--Our province's home of soybeans, Kaiyuan County, again realized a bumper harvest of soybeans this year. The average per-mu yield of the 250,000 mu of soybeans throughout the county reached 305 jin, creating the highest record and leading the province. During the past 2 years, Kaiyuan County has not only implemented the policy of establishing an agricultural production responsibility system, but it has also exerted efforts in scientific planting, and the yields of soybeans have increased year after year. Last year, the per-mu yield reached 255 jin. This spring, the leading comrades of the county committee and the county government conscientiously listened to the opinions of the agricultural science technicians and implemented five technical measures to achieve high yields throughout the county. The superior variety "kai yu No 8" was used in 90 percent of the plots. Phosphorous fertilizers were applied on a wide basis. Equal distance bunch planting was implemented. The soybean seeds were washed. Insect pests were prevented and controlled in time. Damage by aphids and borers was controlled. The insect population affecting soybeans was reduced to under 2 percent. The highest yielding plots produced a per-mu yield of over 540 jin. [Text] [Shenyang LIAONING RIBAO in Chinese 15 Dec 81 p 1] 9296

PHOSPHATE FERTILIZER OUTPUT--Liaoning Province's 1981 phosphate fertilizer output increased 140,000 tons over the planned figure of the same year, a historical record. This increased output had initially eased Liaoning's phosphate fertilizer's supply and marketing conflict. [Excerpt] [Shenyang LIAONING RIBAO in Chinese 8 Feb 82 p 2]

DEVELOPMENT OF LIVESTOCK PRODUCTION IN SUBURBS REPORTED

Shanghai JIEFANG RIBAO in Chinese 22 Dec 81 p 2

[Article: "Livestock Production in the Suburbs Develops Steadily in Readjustment; the City Is 60 Percent Self-Sufficient in Pork, Fowl and Eggs"]

[Text] The proposal by the Central Committee of the Chinese Communist Party to "make suburbs the bases for producing supplementary foods" is being gradually implemented in the Shanghai suburbs. It is estimated that by the end of 1981, the percentage of self-sufficiency in meat marketed by suburban producers will reach 59 percent. The percentage of self-sufficiency in fowl for domestic consumption may reach 70 percent. The percentage of self-sufficiency in fresh eggs may reach 64 percent. The marketed amounts of pork, fowl (including export fowl) and eggs have increased 34 percent, 44 percent and more than onefold respectively over those in 1978, prior to the Third Plenum.

The development of suburban livestock production has these three outstanding characteristics:

Because the food grain production tasks in the suburbs are barely sufficient, because the amount of feed is limited, and because of the actual needs of the city people, the guideline of steadily developing live hogs, egg production, dairy cows, herbivorous livestock and fowl in a big way has been followed. The city's concerned departments have ruled that feed for live hogs should mainly be withheld and kept by the collective, and the state should give appropriate rewards. The feed for fowl should be provided by the state. According to production plans, "fowl can be exchanged for feed" and "eggs can be exchanged for feed;" thus the development of hogs, fowl and eggs has been assured. Domesticated animals such as rabbits and sheep, for which feed is not limited, have increased on a large scale. In 1981, the amount of rabbit fur to be marketed may by five times more than the amount marketed in 1978, and the amount of sheepskin marketed may for four times that marketed in 1978.

In livestock production, the distribution of different kinds of livestock has been emphasized in a relatively rational way according to different natural resources, historical custom and technical and economic conditions. The raising of hogs for pork is popular throughout the whole suburban region. The nearby suburban vegetable-producing areas all have rich sources of swill and city slops and most raise hogs collectively. In the more distant suburban food grain and cotton producing regions, the raising of hogs is mostly carried out by commune member families. The production of sheep follows historical custom. Qingpu, Jiading and Shanghai counties raise lake sheep; Congming County and the two islands of Changxing and Hengsha in Baoshan raise goats. The production of egg laying ducks in nearby Shanghai and Chuansha Counties, where labor is abundant and the economic and technical conditions are better, is mostly confined to duck farms. In the more distant Songjiang, Qingpu, Jinshan Counties, where there are relatively more water surfaces, ducks are raised in enclosures and herded.

Because many communes and brigades in the suburbs have a definite family tradition and a definite foundation of raising domestic animals scientifically, the guideline of "equal emphasis on public and private raising" has been further implemented. In the production of hogs, boars and sows are mainly raised collectively and pork hogs are mainly raised by commune member families. Egg laying fowl are all provided by collective farms. Eggs laid by fowl raised by commune member families are mainly used for self-consumption or for sale at markets in the countryside. Higher intensification and specialization has elevated the standards of scientific breeding, feeding and prevention and control of deseases. The overall implementation of the production responsibility system--mainly contracting work to specialists and linking production to remuneration--has also enabled a large number of livestock farms to turn losses into profits. At present, the percentage of livestock farms making a profit has increased from about 40 percent before the Third Plenum to about 90 percent.

The development of livestock production has also increased the farmers' income. During the past 2 years, each laborer in the suburbs has received an increase of 47 yuan in income from the development of livestock production.

BUMPER HARVEST OF FLUE-CURED TOBACCO REPORTED

Taiyuan SHANXI RIBAO in Chinese 26 Dec 81 p 1

[Article by Yi Xusheng [5030 2485 0581]: "Our Province Realized a Bumper Harvest of Flue-Cured Tobacco; Total Yield of Flue-Cured Tobacco May Reach 60,000 Dan, a Twofold Increase Over Last Year; Self Sufficiency in Cigarettes Increased on a Large Scale"]

[Text] Our province realized a bumper harvest of flue-cured tobacco this year. The 35,000 mu of tobacco fields are expected to produce a total yield of 60,000 dan, a twofold increase over last year. This year will be the third high-yielding year since the founding of the nation. The quality of flue-cured tobacco is also better than in past years. According to statistics of related departments, at present, over 26,000 dan of flue-cured tobacco have already been procured. Of this amount, high-quality and medium-quality tobacco constitute 45.4 percent. This will increase our province's self-sufficiency in raw materials for cigarettes from 5 percent in the past to 25 percent.

The characteristics of this year's production of flue-cured tobacco a[illegible] follows: First, the key counties of the new and old tobacco producin[illegible] realized an overall increase in yield, and the harvests of new tobacco [illegible] are more impressive. The area of flue-cured tobacco in the 12 counties [illegible]ew tobacco regions constitutes only one-seventh the total area of tobacco fields in the province, but the yield of flue-cured tobacco is equivalent to the total yield of tobacco leaves throughout the province last year. The 10 counties in Yanberi Prefecture produced a total of 13,000 dan of flue-cured tobacco, an increase of 26 times over last year. Second, the production of tobacco leaves by the old tobacco regions also revived quickly. Quwo County is expected to produce a total of 20,000 dan of tobacco leaves, an increase of six times over last year. Yicheng County is expected to produce a total of 6,700 dan, an increase of more than threefold over last year. Third, cake manure was applied over four-fifths of the tobacco fields of the whole province, and 70 percent of the area used the superior variety "pan yuan huang". The whole province invited over 420 technical personnel in cultivation and grading to provide technical guidance. All of these measures effectively improved the quality of flue-cured tobacco.

PROVINCIAL AGRICULTURAL WORK CONFERENCE SETS FUTURE TASKS

Taiyuan SHANXI RIBAO in Chinese 16 Dec 81 pp 1,3

[Article by reporters of the Shanxi Peopla's Broadcasting Station and this paper: "Provincial People's Government Holds Provincial Agricultural Work Conference. Relying on Policy and on Science To Hasten Agricultural Development, the Conference Asks Participants to Do a Good Job of Establishing, Perfecting, Improving and Strengthening the Agricultural Production Responsibility System. While Carrying Out Food Grains Production, Economic Crops and Diversification Must Be Developed in a Big Way. In Particular, Cotton and Tobacco Production Must Be Promoted"]

[Excerpts] As the new year is about to arrive, the provincial people's government held a provincial agricultural work conference from 3 to 12 December. The conference, which was held in the spirit of the national agricultural work conference, summarized and exchanged the experience of our province's agricultural and livestock production and the production of commune and brigade enterprises, and studied and arranged the tasks of agricultural production for next year and for the period of the "sixth 5-year economic development plan."

During the conference, comrades from all over the province talked about the great situation on the agricultural front in our province. This year, the drought in some part of our province and the continuous rain during autumn in the southern regions of the province seriously affected agricultural production. But except for the yield of cotton, which registered a drop from last year, the production of other crops was relatively good. The total yield of food grains registered an increase over last year. The production of oil-bearing crops registered the second highest yield since the founding of the nation. The yield of sugar beets increased on a large scale over last year. The production of tobacco, silkworm cocoons, medicinal herbs, vegetables, and fruit all realized better achievements. In livestock production, the total yield of meat and such livestock products as eggs and milk all increased over last year. The total value of production and income from services provided by the whole province's commune and brigade enterprises will be able to reach 2.1 billion yuan. The total income of commune and brigade enterprises still constitutes over 40 percent of the total agricultural income. The income of the collective and commune members also registered new increases. It is estimated that the per capital income from the collective added to the income from sideline production by the commune member's family will increase by more than 10 percent over last year. Throughout the province, a large number of "outstanding families" with large increases in income have emerged. On the basis of the per capita average distributed income from the collective, there have emerged a number of communes with over 200 yuan and a number of brigades with over 300 yuan. There have emerged families with over 1,000 yuan of income and families producing over 10,000 jin of food grains and selling over 5,000 jin of food grains. In most of the poor moutain regions and old regions, which constitute a relatively large portion in our province, the per capita amount of food grains has reached about 500 jin, the per capita income has reached about 60 yuan, and the problems of heating and hunger have been basically solved. Now, the situation in the farm villages throughout the province is indeed a scene of political stability,economic prosperity, happiness, growth and prosperity. Our province was able to realize such good achievements in this year of severe drought on the agricultural front mainly because over the past few years, "leftist" mistakes have been corrected, policy has been relaxed, and in particular, the various forms of production responsibility system have been established and perfected, and the productive enthusiasm of the broad number of farmers has been mobilized.

Comrade Luo Guibo [5012 6311 3134] pointed out in his summary report on the situation and the tasks on the agricultural front in our province: This year, on the agricultural front our province has done a lot of work and has realized great achievements in implementing the lines, principles and policies since the Third Plenum. In the future, implementation of related policies of the party must be continually managed well. The most important problem this winter and next spring is to concentrate on truly establishing, perfecting, improving and strengthening the agricultural production responsibility system. Most of the localities throughout the province have conscientiously implemented the production responsibility system, and the results have been good. But it has been discovered that a few brigades and communes have not properly established the production responsibility system. Some have made simple gestures and established a superficial form. Others have provided statistics but have not actually established the system. It is hoped that the committees of the prefectures, cities and county committees will pay attention to this problem and conscientiously investigate, supervise and encourage the localities to truly implement the production responsibility system. Since the Third Plenum, the Party Central Committee has readjusted the distribution of crops, promoted the development of agricultural production, and established a series of economic policies in order to let the farmers rest and build up strength. In particular, the readjustment of procurement prices of agricultural products has provided more benefit to the farmers, and the broad masses are satisfied. The problem now is to conscientiously carry out these policies and to make sure the promises are fulfilled in order to win the confidence of the people. The basic procurement quotas for cotton and oil-bearing crops which have already been established should be stable and should not be changed lightly. The broad numbers of farmers must be taught to look at the whole situation and to begin by exerting efforts to develop production. Except for a few high-yielding brigades which have established an overly high basic quota in the past, making if difficult for them to produce surplus yields and affecting their productive enthusiasm, generally those with a low basic quota must not be adjusted upward, and those with high basic quotas should not be lightly adjusted downward. The signing of contracts for the procurement of agricultural and livestock products must be firmly implemented by the financial and commercial departments. Starting in 1982, except for the materials uniformly procured and commissioned for procurement by the state, regardless of whether the agricultural or livestock products are for foreign trade or for domestic markets, all agricultural products such as bast fiber skin, walnuts, peanuts, sesame, red dates, melon seeds, medicinal herbs, fruits and such livestock products as pork, mutton, domesticated fowl, hides, wool and eggs must be procured by contract. Procurement of the amounts stipulated in the contracts is guaranteed. Amounts not included in contracts can be procured by the commercial departments on the basis of negotiated price. They can also be processed by the communes and brigades and commune members themselves. All communes and brigades, departments of commerce and foreign trade must strictly abide by the contracts. Foreign trade, commercial and supply and marketing departments must actively guide and help farmers sell agricultural sideline products processed by the communes. brigades and commune members after completion of the procurement contracts. This is an important policy to protect the productive enthusiasm of the farmers. The financial and commercial departments should conscientiously implement this policy. The commercial, supply and marketing and foreign trade departments must change the past business method of manipulating prices only. They must think in terms of providing more convenience to the masses of farmers and in terms of opening the channels of flow of goods. Convenience to the masses and timely procurement must be realized in accordance with the production situation of agricultural and livestock products by the masses of commune members through rationally increasing the establishment of procurement stations. The financial and commercial departments must strengthen ideological education of its staff and workers, and establish the ideology of serving the people; the problems of artificially lowering the grade of goods, artificially suppressing the price of goods, and artificially fixing the scale must be strictly dealt with according to the seriousness of the case.

Comrade Luo Guibo said: To quickly enable agricultural production to progress along the road of a relatively solid rate of development, greater economic benefit and a road whereby the farmers can receive more actual benefit, we should also carry out the following work well in a key way in accordance with the present situation of our province's agricultural production:

1. We must actively develop forestry, livestock production and develop the superiority of the mountain regions. The area of mountain regions in our province constitutes over 70 percent of the total area.

2. The province possesses superior conditions for the development of forestry and livestock production. We must pay a lot of attention to planting trees and grass well, improve the percentage of covering, change the ecological environment, and improve the ability to resist natural disasters. We must pay a lot of attention to the development of economic crops and diversification. The conditions for developing diversification in our province are good. There are many favorable conditions for developing planting, cultivating

mining, and processing. We must further liberate our ideology, break through the confinement of the old ways of thinking. While not relaxing food grain production, we must develop diversification. In planting, we must develop the production of cotton, tobacco and sugar beets in a big way. Especially cotton production must be developed with determination. Cotton farmers must be given food grain subsidies according to state regulations, and the provincial committee and the provincial government must provide all kinds of assistance to the extent possible to stimulate rapid development of cotton production. Sorghum is a superior crop in our province's planting sector. It can be eaten and it is also an industrial raw material. It must be developed according to plan. During the past 2 years, although our province's livestock industry progressed somewhat, the number of female livestock has been drastically reduced. If this situation is not changed, the development of the livestock industry will necessarily be greatly affected. Family sidelines of commune member masses must be actively supported to help them develop such domestic fowl and domesticated livestock as rabbits, chickens, ducks, bees, silkworms, and martens as quickly as possible. Commune and brigade enterprises are important components of diversification in farm villages. They are forceful pillars to strengthen and enlarge the collective economy, and they are an important means for the farmers to become rich. Implementing the agricultural production responsibility system does not mean to shrink or chop away commune and brigade enterprises, but to steadily develop commune and brigade enterprises even better during readjustment. The developing commune and brigade enterprises must emphasize and pay attention to processing agricultural sideline products, local specialty products, livestock products, and follow the road of joint ventures in agriculture, industry and commerce. Commune and brigade enterprises can develop cooperation between enterprises both inside and outside the province, but when cooperating with enterprises outside the province, unified leadership and management must be strengthened.

3. We must quickly improve the standard of scientific planting, fully develop the function of scientific and technical personnel. To enable agricultural production to progress along the road of steady development, we must pay attention to the productive force of science and technology and we must truly include scientific planting, scientific cultivation of livestock and scientific management on the daily business agenda of the party committee and government at each level. Just as in establishing, developing and perfecting the production responsibility system, they should be carried out well and intensively. We must pay a lot of attention to developing the function of scientific and technical workers in agriculture and livestock production and the function of model laborers so that traditional agricultural techniques can be closely combined with modern agricultural techniques to stimulate the development of agriculture and livestock production.

4. We must insist on untiringly developing capital construction of farmland, changing the conditions of agricultural production, and improving the ability to resist disasters. We must upturn and improve the presently available cultivated land well on a broad basis. We must pay a lot of attention to increasing the application of organic fertilizers. We must build up large stockpiles of phosphorous fertilizers and small phosphorous fertilizers well,

and solve the problem of the deficiency of phosphorus in the soil. Here, I especially want to talk about the problem of water. During the last few years, because of drought and other conditions, most of the reservoirs and shallow wells have dried up, and the underground water level has seriously dropped. The reserve of underground water has decreased on a large scale. The supply of ground surface water is scarce, so great difficulties have occurred in the use of water for industry, agriculture and living. Our province does not have many ways of developing water sources. At present, we can only take effective measures to control the use of water and to conserve the use of water. The presently available water conservancy projects must have complete equipment. They must be strengthened and maintained to prevent leaks and seepage. In irrigation, border irrigation must be implemented. Flood irrigation must be prevented. When industry, agriculture, offices or schools want to sink deep wells, they all must ask for approval by the water conservancy departments above the county level.

BRIEFS

TOBACCO PRODUCTION PROBLEMS--In 1952 there were 110,000 mu of tobacco fields with a total yield of 14.97 million jin. By 1980, the area had dropped to about 10,000 mu with a total output of only a million or so jin; moreover, the quality was not good, thus seriously effecting the production of Shanxi's tobacco industry. Each year a large amount of raw material had o be shipped into the province, reducing the provincial economic income and the income of peasants in the tobacco region of the province. Our serious attention could not but be drawn to this matter. The fact that smoking is harmful to one's health is common knowledge to everyone as is the fact that it is difficult to quit smoking. The supply of cigarettes in the marketplace is limited. The masses have their opinions about this and this too is common knowledge. But for the present, with regard to developing a diversified economy and increasing the peasants' income, there is still a strong need for the suitable development of tobacco production in areas suitable for raising tobacco. The income from growing tobacco is relatively high. In Yanbei Prefecture the three year average yield is 387 jin per mu and each mu can bring in 348 yuan. BRIEFS

1981 AGRICULTURAL PRODUCTION--Provincial Governor Liu Minghui [0491 2494 6540] said in his administration report at the fourth meeting of the province's Fifth People's Congress yesterday that in 1981 our province's agriculture again realized overall bumper harvests on the foundations of the large increased yields of the previous year. The situation in the farm villages is very good. Governor Liu Minghui said that in 1981 our province further implemented the various economic policies in farm villages promulgated since the Third Plenum. The province mainly grasped the two important links of establishing and making sound the production responsibility system on an overall basis and developing diversification. Overall increases were realized in agriculture, forestry, livestock production, sideline production and fishery. The total value of agricultural production is expected to increase 5.4 percent over 1980, and there may actually be a greater increase. The production value of economic crops is expected to increase 33.8 percent. Food grains, major economic crops and the number of livestock will all reach the highest levels in history. The total yield of food grains may reach 17.8 billion jin, an increase of 500 million jin over 1980. Among the major economic crops, flue-cured tobacco will increase by 59 percent, oil-bearing crops will increase by 48.9 percent, and sugar cane will increase by 19.3 percent. The commercial commodities percentage of agricultural products will also increase from 29.6 percent in 1980 to 34.5 percent. [Text] [Kunming YUNNAN RIBAO in Chinese 1 Jan 82 p 1] 9296

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 1, 20 Feb 82 pp 1-7

TEXT OF ENGLISH ABSTRACT: Fusarium wilt and verticillium wilt disease of cotton were the most serious diseases in China and caused the loss of about 200,000 tons of ginned cotton per year for several years. Since the establishment of the Association of Integrated Control of Cotton Fusarium Wilt and Verticillium Wilt Diseases, many achievements in scientific research have been obtained.

This paper is a general review of the research work in China on these two diseases during the past 10 years. The topics hitherto undertaken include the studies on species and physiological forms of cotton Fusarium wilt and Verticillium wilt pathogens, breeding for resistance, investigations on plant resistance, host plants, epiphytology studies, seed treatment and integrated control of these two diseases.

By means of resistant variety planting of cotton, about 150,000 tons of ginned cotton have been retrieved every year in recent years.

TITLE: "Studies on the Host Plants of Wheat Rosettle Stunt Virus"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 1, 20 Feb 82 pp 8-13

TEXT OF ENGLISH ABSTRACT: The host plants of wheat rosettle stunt virus (WRSV) is very widespread. Among the 10 species tested, including 49 varieties of cereal crops, wheat, barley, rye, triticale, oat, millet, proso and certain varieties of sorghum (Baiping and Luyiwaibo) were susceptible; corn and rice were resistant. Among the three grasses tested, species such as wild oat (*Avena fatua*), showy chloris (*Chloris virgata*), fingergrass (*Digitaria adscendens*), etc., were susceptible host plants; the other 19 species, such as barnyard grass (*Echinochloa crusgalli*), goose-grass (*Eleusine indica*), etc., were resistant host plants. No carrier host plants have been discovered. The results of the inoculation experiments demonstrated that the host plants of WRSV were very similar to those of the northern cereal mosaic virus (NCMV) reported in Japan. There were, however, minor differences. WRSV could infect yellow bristlegrass (*Setaria lutescens*) and individual varieties of sorghum, whereas NCMV could not. WRSV could not infect barnyard grass, whereas NCMV did. The authors suggest that WRSV may be a strain of NCMV.

TEXT OF ENGLISH ABSTRACT: The "damping off disease" of cotton seedlings was reported to be caused by *Phytophthora parasitica* Dast in many countries. In recent years a species of phytophthora causing "damping off disease" of cotton seedlings has been prevalent along the Changjiang River, but it has not been identified. We studied the morphological and physiological characteristics of this fungus and found that it is identical morphologically to *P. boehmeriae* which caused boll blight in China, but its capability of starch utilization was quite different. Therefore we are of the opinion that the cotton seedling disease fungus in China may be a biotype of *P. boehmeriae* Sowada.

TITLE: "Breeding of *Geng* Type Hybrid Rice Liyu 57"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 1, 20 Feb 82 pp 38-42

TEXT OF ENGLISH ABSTRACT: The objectives for the breeding of *geng* type hybrid rice Liyu 57 and the three-line set of a combination for a strong heterosis were described in this paper. The heterosis of the hybrid and its morphological characteristics as well as the evaluation of the productivity were also described. Liyu 57 exhibits a heterosis derived from both its *geng* and *xian* parents and is characterized by semi-dwarf plant height as in *xian* rice and cold endurance as in *geng* rice. The F_1 of Liyu 57 has a wide adaptability and high resistance to adversity (resistance to drought and waterlogging, tolerance to poor soil fertility) when sown as early rice in the single-cropping area in Liaoning Province or rotated with wheat in the double-cropping areas in Beijing and Tianjin districts, and along the Huanghe River and Huaihe River basin where it has shown a high yield potential.

ORG: All of the Institute of Crop Germplasm Resources, Chinese Academy of Agricultural Sciences, Beijing

TITLE: "Investigation of the Big Grain Germplasm of Wheat in China"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 1, 20 Feb 82 pp 43-48

TEXT OF ENGLISH ABSTRACT: Since the founding of the PRC, the TKW (thousand kernel weight) of wheat varieties has been getting bigger and bigger. The mean TKW of the varieties was 31.4 g at the time of the beginning of the liberation, 35.3 g in the 1950's, 38.6 g in the 1960's and 40.5 g in the 1970's.

The average TKWs of varieties bred in various provinces were different. They were restricted by ecological conditions. The whole country was divided into four regions. When we introduced a variety from one region to another, it showed a difference in TKW because the ecological conditions were different.

[Continuation of ZHONGGUO NONGYE KEXUE No 1, 20 Feb 82 pp 43-48]

According to the results of our investigation on the size of wheat grains, we are of the opinion that the criterion for the TKW of big grain germplasm should be over 45 g.

Analysis of the pedigrees of big grain wheat varieties shows that the origins of these varieties are as follows: about 29.12 percent are derived from "Abbondanza," about 26.67 percent from "Orofen," 22.10 percent from "Nan Da," 5.96 percent from "Funo," with the total being 83.85 percent. The varieties whose TKWs are above 60 g have a variety of parentage, consisting not only of *T. aestivum*, but also *T. turgidum*, *T. durum*, *T. polonicum* and *Secale cereale*, etc.

TITLE: "Studies on the Rules of Assimilate Accumulation and Nutrient Absorption and Distribution in the Summer Maize Plant. I. Rules of the Dry-matter Accumulation and the Variation of Water-soluble Carbohydrates and Free Amino-acid Contents"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 1, 20 Feb 82 pp 56-64

TEXT OF ENGLISH ABSTRACT: The pattern of the process of dry-matter accumulation in the whole period of growth in a single maize plant appeared in the form of an S-shaped curve. The average dry-matter was 2.26 grams, and the average net assimilation rate was 8.93 $g/m^2/day$. Analysis of the ratio of watersoluble carbohydrates to free amino acids in the maize plant showed that the nitrogen metabolism played a dominant role at the early stage of growth, both the nitrogen and carbon metabolisms were vigorous at the middle stage, and at the late growing stage the carbon metabolism became predominant.

TITLE: "Research on the High-yield Factors and the Population Development of Peanuts"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 1, 20 Feb 82 pp 71-75

TEXT OF ENGLISH ABSTRACT: A high yield of peanuts with a range from 1003.9 - 1303.2 jin/mu was obtained from 46 plots in 1979-1980. The factors constituting a high yield peanut were found to consist of an actual harvest of 10,500-15,000 plants per mu, 17.2 - 25.0 pods per plant with a total number of 256,000-298,000 pods per mu, and 231-256 pods per 0.5 kg; the seedling population grew strongly and rapidly during the early growing stage, while in the middle growing stage the plants grew steadily and stoutly, and did not show withering of the main stems in the late growing stage; the maximum LAI was 4.5 - 5.5; the best rate of net assimilation was 6.9 - 9.5 $g/m^2/day$, with a total biomass yield of 1840-2404.8 jin per mu.

TITLE: "Diagnosis of Transmissible Gastroenteritis (TGE) in Pigs by Examination of Tonsillar Smears with Direct Immunofluorescence Technique"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 1, 20 Feb 82 pp 84-89

TEXT OF ENGLISH ABSTRACT: The results of examination of tissue smears from TGE experimentally infected pigs with the direct immunofluorescence (IF) technique are described. In pigs from the 2nd to 9th day after infection. fluorescence of antigen was observed in 100, 78, 78, 56, 22 and 11 percent of the smears prepared from the tonsil, jejunum, mesenteric lymph node, lung, liver and kidney respectively, and the spleen was negative. In pigs from the 13th to 41st day after infection the positive rate of tonsil was 60 percent and that of the jejunum was only 6.6 percent, while those of the other tissues almost became negative. The total positive rate of the tonsil was 75 percent, and that of the jejunum 33.3 percent.

[Continuation of ZHONGGUO NONGYE KEXUE No 1, 20 Feb 82 pp 84-89]

The accuracy of diagnosis by the direct IF method was confirmed by the results of susceptible pig inoculation and virus isolation in fetal pig kidney cell culture from tonsillar tissues of 25 symptomless, naturally infected adult pigs, and by the detection of TGE neutralizing antibodies in 13 naturally infected pigs showing clinical symptoms which had given positive tonsillar IF results. This procedure of examination is considered to be superior to the jejunum examination. A tonsillar drill was devised for the collection of tonsillar materials from living pigs. Good results have been obtained in the application of this method to the diagnosis of TGE in field outbreaks, epidemiological investigation and import inspection.

TITLE: "Regionalized [Erosion] Control of Grasslands on Loess Plateau"

SOURCE: Nei Monggol ZHONGGUO CAOYUAN [GRASSLAND OF CHINA] in Chinese No 2, Jun 81 pp 7-9, 56

ABSTRACT: The problem of erosion is very serious in loess plateau, sending as much as 1.6 billion tons of sand into Huanghe every year. Including the wastelands, 70 percent (sic) of the plateau are forests, 15 percent farmland, and 75 percent grasslands. One percent of the sand comes from the forest, 49.5 percent from the croplands, 15.2 percent from grasslands, and 112.5 percent (sic) from fallow lands. In terms of erosion control; therefore, aside from emphasizing water and soil conservancy measures of the fields, the grasslands should also be taken care of to prevent runoff, to establish foundations for animal husbandry, and to reduce silting of Huanghe. For the purpose of achieving these goals, the paper divides the grasslands of the plateau into 5 regions: (1) Grasslands of the windblown sand region of the northernmost area of the plateau; (2) A region of hills and ravines south of the first region and north of the forest grassland; (3) Grasslands of the plain region of river valleys; (4) The highland grasslands with the thickest loessial deposits of the plateau; (5) The mountainous grasslands of elevations below 2000m. Grass species suitable for revitalizing each of these regions to transformit into pastures are provided as well as essential measures of wind and water erosion prevention.

TITLE: "Solar Radiation Resources of the Hulun-Boir Steppe"

SOURCE: Nei Monggol ZHONGGUO CAOYUAN [GRASSLAND OF CHINA] in Chinese No 2, Jun 81 pp 16-19, 6

ABSTRACT: Hulun Boir steppe is located in the northeastern part of China at about 50° N.Lat. It is one of China's pastoral regions of the greatest daylight resources. In May-Jun 75 and Apr-Aug 76, the authors measure its direct solar radiation spectrum and computed its spectral elements. Combined with the 20-year radio observation data of the Hailar Weather Station, the intensity of ultraviolet, visible, and infrared radiation of the growing season of crops (May-Aug in that region) is analyzed. The photosynthesis potential of the steppe is estimated and compared with other regions of China, such as Shanghai, Guangzhou, Chengdu, etc. The paper concludes that although the climate of the steppe is very cold, with a short frostfree period of only about 110 days, the solar radiation is intense and mostly concentrate in the crop growing season, which is also the season of concentrated rainfall to provide very favorable conditions for the crops to utilize the light energy fully.

SOURCE: Nei Monggol ZHONGGUO CAOYUAN [GRASSLAND OF CHINA] in Chinese No 2, Jun 81 pp 30-34

ABSTRACT: An experiment has been conducted since 1979 with mixed seeding of alfalfa and such forage species as smooth brome [Bromus inermis], common crabgrass [Digitaria sanguinalis] wild barley, or orchardgrass [Dactylis glomerata] in different amounts and different ratios to compare the unit yield. The experimental farm of the institute is located at 116°04' E. Long. and 43°57' N. Lat, 989.5m in elevation. It has light chestnut soil, pH 7.6-7.8, with a layer of humus about 20cm in thickness and coarse or fine sand below. Seeding is done in late May in small plots of 2 x 6 m. Before seeding, 5,000 jin/mu of mixed farm fertilizer is applied while turning and leveling the soil. Of the various combinations, the yield is found to be the highest when the legume [alfalfa= Medicago denticulata] is seeded in alternate rows of 15cm in width at a ratio of 1 : 1 with smooth brome. Details of the experiment are reported.

TITLE: "Studies on the Agricultural-Biological Characteristics of White Clover"

SOURCE: Nei Monggol ZHONGGUO CAOYUAN [GRASSLAND OF CHINA] in Chinese No 2, Jun 81 pp 35-40

ABSTRACT: White clover [Trifolium repens] is a native of Europe, in eastern Mediterranean or western Asia Minor. It is said to be cultivated in England as early as 1707 before spreading to the North American continent. Due to the fact that it is a fine leguminous pastoral forage and suitable for lawn decoration as well, it is soon extended to all areas of the world. In China, it has also been used for the pasture as well as the parks. It is now distributed in the wild in Sichuan, Guizhou, Xinjiang, etc., spreading from the original cultivated form. A study was conducted in 1974-80 in Ya'an Prefecture of Sichuan to observe its distribution and ecological adaptability in the basin, in the mountains bordering the basin, and in the Sichuan-Xizang Plateau, i.e. in the region of 26°-34° N.Lat. and 95°-110° E.Long. of an elevation of 180-4200m. Variations in flower and seeds induced by different environmental conditions, variations of yield in soils of different fertility, and other findings are reported.

TITLE: "Current Condition of Clam Resources in Bohai and Investigation Into Measures for Restoring Them"

SOURCE: Shanghai HAIYANG YUYE [MARINE FISHERIES] in Chinese No 1, 25 Jan 82 pp 16-19

ABSTRACT: Clam [Arca granosa] is an important economic shellfish of Bohai. Its production in 1976 reached the historical level of 40,000 tons, amounting to a quarter of the marine products of Hebei Province. Its production has dropped rapidly since then and the clam fishing has practically become worthless. There are 2 views concerning the cause of such large scale reduction of clam resources: One is the change of the ocean floor and the water quality induced by the violent earthquake of 1976; the other is the extreme low temperature of the winter of 1976 causing clams to freeze to death. According to net dragging and diving studies carried out in Jul 77, the ocean floor of the areas of clam distribution (map included) remains soft silt. The reported magmatic black water was never observed. Clams inhabit offshore waters all year long. When the atmospheric temperature of the coastal region was down to -12.6°C in the winter of 1977, there was no sign of dead clams at all. The author believes that although complex natural and artificial reasons may have caused the reduction of clam resources, excessive harvesting is the major factor. He advocates a rotation of areas open for fishing, shortening the fishing season to 5 months a year, and closing all areas from late Jun to early Sept, the reproductive season for clams. Measures should also be found through scientific research to promote propagation, to protect the clam resources, and to transplant clams to these areas which are most suitable for their growth.

SOURCE: Beijing LINYE KEJI TONGXUN [FOREST SCIENCE AND TECHNOLOGY] in Chinese No 11, 11 Nov 81 p 6

ABSTRACT: For the purpose of finding new ways of breeding Camellia oleosa, research on its anther culture to develop haploid plants was carried out in 1976-80. Green budding points and roots resulting from evolving anther callus tissues have just been obtained. Following various unsuccessful attempts, roots were obtained under the condition of constant temperature after the anther was pre-cultured in liquid medium for 12 days and transferred onto a solid medium. When the anther callus was cultured with the medium of N_6(3% cane sugar, pH 5.8) with BA (2) + IAA(0.5) + 5Br (0.5) + riboflavin(1) added for 60 days under the room temperature of about 18°C and lighting condition of 10-12 hours/day with a fluorescent lamp, green budding points appeared; these budding points extended obviously after they were cultured for another 10 days. But due to limitations of objective factors [not specified] and contamination, a complete seedling was not obtained. Details of the experiment are reported.

TITLE: "Approach to Improving the Effectiveness of Air Seeding"

SOURCE: Beijing LINYE KEJI TONGXUN [FOREST SCIENCE AND TECHNOLOGY] in Chinese No 2, 10 Feb 82 pp 15-17

ABSTRACT: Since the adoption of the air seeding technique in China in 1958, 170 million mu have been experimented and 70 million mu of adult and young forests have survived, amounting to 15 percent of the country's total forestation area. Judging from the afforestation schedule, the result of air seeding remains to be less than satisfactory and many problems are in need of studies. Due to such factors as flight altitude and speed, direction and speed of wind, seeding equipment, the length and width of the area to be seeded, etc.some places are seeded repeatedly and others are missed altogether. There are also problems concerning the natural conditions which vary a great deal from the north to the south, from one mountain slope to the other, etc. Characteristics of the species also present some problems. At present, the 3 species of Pinus massomania Lamb, P. sinensis [P. tabulaeformis Carr.?] and P. yunnanensis are the major ones used in air seeding. They are highly drought resistant. The survival rate should improve.

WHEAT EXPERT OUTLINES PROBLEMS IN MODERNIZATION OF AGRICULTURE

Beijing GUANGMING RIBAO in Chinese 1 Feb 82 p 2

[Article by Correspondent Li Linhe [2621 2651 3109]: "Several Problems in the Modernization of China's Agriculture--A Visit With Peasant Wheat Expert Liu Yingxiang [0491 2019 4382]"]

[Excerpts] China's famous peasant wheat expert and vice chairman of the Henan Provincial Agricultural Commission, Liu Yingxiang, visited the United States on invitation last October to participate in the Second Meeting of the Sino-U.S. Joint Commission on Scientific and Technological Cooperation in the field of Agriculture. After he made a speech at the meeting, delegates from every country unanimously acclaimed him as "the man with the most experience at this meeting."

At the conclusion of the meeting, American agricultural scientist Dr George Keyworth and his wife accompanied him on a special trip to many places. Old Liu said that during this visit to the United States I not only saw the high degree of mechanization, and extensive use of farm chemicals that a developed economy has provided their agriculture, but I also saw the serious consequences for agriculture that these advancements have brought about. As a result of large scale use of chemical fertilizer over a long period of time and the lack of microbiological activity, the soil structure of many places has been damaged. As a result output is not high, even a decline in output is possible. American government officials at the conference said that unless this problem is solved, by the end of this century the soil structure of all their farmland will be damaged. In addition, according to research done by the American National Science Institute, 70 percent of the chemical fertilizer used is not absorbed by the crops, but is either carried away by ground water or is volatilized into the air. This is not only an extremely great waste, but also pollutes running water and the atmosphere. The fruit of crops on which chemical fertilizer and pesticides has been used are themselves polluted. As a result, the United States is now anxious to take the path of organic agriculture. The government has promulgated laws whereby those farms not using chemical fertilizer, pesticides, or herbicides are issued organic farm certificates. Products from farms holding such certificates may be sold at three, four or five times the usual price, and they are very popular.

Old Liu said that China with a population of 1 billion has an extraordinarily copious source of organic fertilizer such as human feces. To take Henan Province as an example, figuring a daily excretion of 3 jin of feces and urine for each of its 73 million population, this means 80 billion jin each year, or an average 750 jin per mu. Henan Province also has more than 6 million head of large cattle, more than 13 million swine, 11 million sheep and goats, 12 million rabbits, and 110 million chickens. Were all the cattle and poultry manure to be used, it would be sufficient to replace all the chemical fertilizer presently used and to improve the soil as well, making the ground more fertile the more it is farmed. Liuzhuang Production Brigade in Qiliying, Xinxiang County uses 10,000 jin per mu of organic fertilizer annually for wheat yields of 800 jin per mu, and corn yields of 800 jin per mu. If every place were to devote the same attention to organic fertilizer as Liuzhuang, the province's grain output would double without question. However, many places in our provinces let large quantities of human and cattle dung disappear, and stalks and stems are burned. Organic content of soil in Liuzhuang is about 2 percent, while it is only zero point something in many other places. I am not denying the role of chemical fertilizer. Chemical fertilizer is a quick acting fertilizer, which when used at certain times increases yields strikingly. What I am saying is that use of organic fertilizer should be paramount.

Liu Yingxiang believes that China's traditional organic agriculture is in need of renewed recognition and renewed evaluation. He proposes organization of experts for conscientious study and diligent summation of China's several thousand years of abundant experiences in agriculture. We must take our own road in the modernization of agriculture.

"Need for Serious Attention to Small Planting Industry, Small Aquatic Breeding Industry, and Small Processing Industry"

Liu Yingxiang said that delegates to the conference from all countries emphasized vigorous advocacy of small-scale biointensive farming methods and development of family style food production. By so-called small-scale intensive farming, it refers to the growing of numerous things on small tracks of land: radishes, cabbage, tomatoes, cucumbers, etc. These can fully and effectively use natural resources and human resources for great increases in yields per unit of area. According to experiments performed by America's California State University, small area growing of cucumbers can produce yields nine times the American average. In places in which the weather is relatively mild, a family of five needs plant only 7 or 8 li [4.7 to 5.3 square meters] to meet the entire family's needs for vegetables. Moreover the expenditure of human labor would not be great, averaging less than 1 hour per day. This is not only something within capabilities, but it would also be very good physical exercise for those who do mental labor. While traveling around in the United States, I noticed that many homes plant food crops in flower gardens. On rooftops and patios, soil has also been added to grow crops of various kinds. On wasteland slopes in the suburbs a great deal of growing is done. A single vegetable garden may grow five or six crops each year of several different kinds. Crops that grow at different speeds are planted, and intercropping of varieties is done for harvests of different kinds at different times. This method both keeps down weeds and prevents disease and insect pests. Intercropping of lettuce and tomatoes, for example, can get rid of many kinds of insect pests that hurt tomatoes. Raising of domestic fowl is also an intensive method. We visited one farm where the feed house had several storeys. On the top storey was rabbits; on the second storey was chickens; and on the bottom one was geese. What the rabbits did not eat, the chickens ate, and what the chickens did not eat, the geese ate. Earnings were between $6,000 and $7,000 per year.

Old Liu was full of confidence and hope about development in China of small planting industry, small aquatic breeding industry, and small processing industry. He said that following institution of systems of responsibility for agricultural production, everywhere in China "outstanding households" appeared. The role of these "outstanding households" should not be deprecated; they have established a model for people. How do they become outstanding? One very important way is by reliance on the "three smalls." RENMIN RIBAO reported that Zhao Qingshan [6392 7230 1472], a commune member in Hebei Province, used a courtyard of slightly more than 0.2 mu to raise hogs and fish, and to grow many things such as cucumbers, celery, radishes and grapes. Some products he processed for sale. He was able to recover costs and had an annual income of more than 3,000 yuan to support 10 people. Right now some cities are experiencing a vegetable shortage. Were all of us to do as Zhao Qingshan did, we would be able to eat anything without any problems. A single hen lays 15 jin of eggs a year. A family of five could raise 15 hens without much trouble for an average of 45 jin of eggs per person per year. However, if one were to depend on a large chicken farm to get this number, that would not be easy. The country would have to spend a lot of money, and if things did not turn out well, it would lose it. China is characterized by a large population relative to land, and it has to make the most of its advantage in having a large population and households. With the liberalization of various rural policies, in particular, commune members have private plots, fields for which they are responsible, and small unused tracts of land, very good conditions for carrying out the "three smalls."

"Most Important Is to Have the Peasants Master Science and Technology"

In talking of this problem, Old Liu sighed with emotion. He said that to realize the modernization of agriculture, he believes there have to be three strengths. One is the strength of leaders. Leaders at all levels must understand science and not resort to blind guidance. Next is the strength of scientists. We scientists and technicians are few in number, but the waste of peoples ability is substantial. Third is the strength of the direct producers--the peasants. These are the keys. Unless advanced science and technology are used to arm the peasants, leadership cadres and scientists will more and more become leaders without a following, and the best research results will not be able to be applied and promoted. In Henan Province, some plots produce wheat yields of 1,000 jin per mu. There are 800 to 900 jin per mu communes and brigades, more than 700 jin per mu counties, and more than 500 jin per mu prefectures. But no one has studied well or summarized well their experiences. Were their existing experiences to be summarized and promoted, the province's total output could be multiplied several times over.

Liu Yingxiang mentioned that now there is a trend toward unpopularity about being in the front line. In the raising of wages and evaluation of positions, it is credentials that are looked at, but insufficiently serious attention is given to actual work accomplishments. Consequently, some scientists and technicians do not want to go to the front line of production, but prefer to close the door and engage in research. This is not to say that laboratory research should be eliminated, but rather that conduct of research should not be divorced from the realities of production, and from the masses. To realize the modernization of agriculture without raising the scientific and technical levels of the 800 million peasants is so much empty talk. Following institution of systems of responsibility for agricultural production, peasant fervor for the study of science and the use of science is very high. In the propagandizing and popularizing of agricultural technical knowledge, all jurisdictions have thought up numerous methods and created numerous systems. We must continue to strive. Once the untiring hands of the peasants are guided by heads full of science, an earth-shaking change will come about in China's agriculture.

METHODS TO IMPROVE PERSONNEL MANAGEMENT DISCUSSED

Tianjin KEXUEXUE [SCIENOLOGY] in Chinese No 5, 20 Oct 81 pp 44-46

[Article by Zhu Xinmin [4281 2450 3046]: "Ways to Improve Management of Agricultural Scientific and Technical Personnel"]

[Text] The central issue in improving the management of agricultural scientific and technical personnel is to steadily expand the work force, restructure the organizations, and mobilize the initiative of the personnel. Below are a few ideas on ways to improve the management of personnel.

1. Actively Train Personnel for Technical Popularization

The Chinese Academy of Sciences classifies scientific research into four levels, namely, basic research, applied basic research, applied research and popularization research. In order to serve the purpose of production, the academy puts 30-40 percent of its work force on applied research, 5-10 percent on popularization research. Agricultural research units below the provincial level work mainly on applied and popularization research and should devote more of their forces to popularization research. The provincial academy should use 20 percent of its personnel for this purpose; prefecture institutes, over 50 percent; while county institutes should devote their entire force to popularization research and work. Currently practically all the scientific and technical personnel in the provincial academy and the prefecture and county institutes are engaged in applied research (about 40 percent are working on seed breeding). This state of affairs should be changed quickly. Agriculture is restricted by natural conditions, so it is of no advantage to impose arbitrary uniformity over a large area. The key to popularization work are the grass-roots communes and production brigades. If we are to provide each production team with one middle-level technical personnel then we would need 30,000 of them. If we are to provide each production team with one primary-level agricultural technician, then we would need 300,000 for the whole province. It can thus be seen that training popularization personnel and expanding the number of them to popularize technical skills are important parts of work in personnel management. To train the necessary personnel, we should explore diverse means and methods. In addition to existing colleges and universities, agricultural middle schools should be set up in the countryside, while research units at the provincial, prefecture and county level should all take on the task of training personnel, and produce results and qualified personnel to serve the purpose of production.

2. Raise the Level of Scientific Research Personnel

Scientific Research work in our province so far has been mainly on introducing achievements from outside and summarizing them. Creative projects take a secondary place. Take improved varieties of seeds, for example. Over 40 percent of the province's technical force is working on breeding. Only 23.5 percent of the seeds used are staples being used in production or selected from promising varieties by our own technicians. These are sown to limited areas and few varieties have been passed on to other provinces. To change this situation, aside from improving conditions and management, the main effort should be on raising the professional level of the personnel. The main targets of training should be:

(1) Train academic leaders. Generally speaking, leaders should be experienced and have done creative work in their specialized fields and have the ability to lead a group of people in research and contribute to progress in their fields. The average age of the 160 middle-level research personnel in the provincial academy is 48.1. The average age of the 50 supervisors of the 59 completed projects of 1978-79 is 45.3. Of these, 50 percent are 45 or under, the youngest is 34. This shows that it is best to train people under 45 as research leaders.

(2) Train research mainstays. Generally speaking, research mainstays are those who can undertake and complete a task independently, organize research work, produce design plans, and sum up experimental work. The present mainstay personnel are all over 40. To bridge the age gap, we should select people under 45 to be trained as mainstays.

(3) Raise the level of basic disciplines, experimental techniques and foreign languages. Because of the 10-year turmoil and increasing obsolescence of knowledge, everyone faces the question of re-learning and being re-educated. Each person should concentrate on some specialty, and work and learn at the same time.

In training and raising the level of research personnel, we should make full use of existing academic leaders and veteran scientists in local units, regions and provinces. We should also send our people in a planned way to other units, provinces or countries to study. This is of strategic significance and should be carried out in a planned way and without delay.

3. Readjust the Composition of Scientific Research Personnel

To suit the laws of development of sciences and do a good job of scientific research, we should make suitable readjustment of the composition of research personnel. First of all, there should be a proper proportion of personnel in the different disciplines so that research can be conducted in depth and comprehensively. As far as agricultural research units go, what we lack at present are people versed in basic disciplines, applied math and computing techniques, economics, and integration. The United States devotes much effort to this aspect, their engineering and economic personnel, especially, account for 8 percent and 10 percent respectively. We should increase personnel in these areas according to the needs of different units, the proportion to be controlled, say, at 20 percent. Second, through readjustment to more satisfactory padoda-shaped structures should be formed in technical level (high, middle, primary), division of work (researchers, assistants, support personnel), age (old, middle-aged, young). Third, the proportionate composition of administrative personnel, technical personnel and workers should also be readjusted. We should, through training, turn non-professionals into professionals, and gradually reduce the number of workers through the use of machines. The target is to gradually change the proportions from 1:2:4 to 1:5:4. In other words, for every manager, there should be one researcher (or leader), two assistants (or chief researchers), two support personnel, and 3-4 workers.

4. Implement Policies and Make Use Rationally

Like other scientific and technical personnel, agricultural scientific and technical personnel are a part of the working class, a force the party relies on. In recent years, the central and local governments have adopted a series of principles and policies that have mobilzed the initiative of the scientific and technical personnel. But some problems remain to be studied.

First, insist on the socialist principle of material benefits. Among the agricultural scientific and technical personnel now, there is a universal tendency toward equalitarianism. The socialist principle of material benefits has not been put into practice with units and individuals that have made outstanding achievements in science in technology. We should practice the system of personal responsibility for one's area of work. Scientific and technical personnel who have made outstanding achievements should be honored politically, be given appropriate technical titles, and receive appropriate remunerations. The same goes for whole units, so as to encourage people to work hard at mastering foreign languages and basic theories, at studying popularization of science and technology and scaling the heights of science.

Second, insist on training with definite goals and utilizing one's strong points. A research unit should be a collective made up of different kinds of personnel and having definite research capabilities. This collective should have both specialized personnel and comprehensive personnel; both professional personnel and basic and technical personnel; both research personnel and management personnel. After receiving the necessary grounding, the different kinds of personnel should be trained to reach definite goals, with their strong points being put to full use. We should not use professionals as non-professionals, and vice versa.

Third, mobility of personnel. Mobility of personnel is good for both individual growth and scientific progress as a whole. Mobility is also an objective need. Some people may be suited for research, others for teaching or popularization or management. If their present posts cannot make full use of their strong points, mobility can solve the problems. Or, when mutual relationships are not harmonious, and no amount of political-ideological work can achieve expected results, certain mobility should be allowed. Mobility is also necessary to solve such problems as husband and wife living in different places. Ours is a socialist country which is different from capitalist countries, and there cannot be a wide range of free mobility. Perhaps the authorities can apply the following measures to promote mobility: 1) Research institutes should have the authority to transfer and recruit personnel; 2) promote large-scale research cooperation; 3) invite lecturers or send people out for study or refresher courses; 4) send out study groups and organize academic exchange; 5) allow project supervisors to select their own assistants and support personnel.

Fourth. Open all avenues for people of talent. Modernization of agriculture needs large numbers of qualified research personnel, therefore we must open all avenues for people of talent and give them a chance to develop. Aside from training personnel through various channels, we should encourage young people to study on their own. The state should establish necessary systems to allow people who study on their own to take examinations or be assessed at designated places and be issued certificates. Once accepted by a work unit, they should receive equal treatment.

Fifth. Create conditions for scientific research. To bring the role of scientific research personnel into full play, we must provide the necessary instruments, facilities, books and reference materials. Some Japanese friends who in 1980 visited our provincial academy of agricultural science said that while the grounds and buildings were adequate, instruments and equipment were most inadequate. In recent years in the provincial academy, the expenditure for each person each year averaged 2,000 yuan; in the prefecture institutes, 1,500 yuan; in the county institutes, only 1,000 yuan. After deduction of staff wages and miscellaneous expenditures, little was left to purchase instruments and books and to use for scientific research projects. If this situation is not changed, there will be a great waste of qualified personnel. To change this situation, we should, first, increase investments and, second, economize on expenditure and increase income, and ensure key projects and make rational investment.

Sixth. Establish evaluation and promotion systems. The state has already made stipulations regarding promotion of scientific and technical personnel. We also need a complete set of systems to implement the stipulations regarding promotion of scientific and technical personnel. We also need a complete set of systems to implement the stipulations well. Since there is a great lack of qualified personnel in our country, we need to move faster. We should hold evaluations once a year to accelerate the growth of qualified personnel. The main content of evaluations should include a person's professional level, foreign language level, scientific research and work ability, scientific research achievements and work performance, contribution toward the development of agricultural production and its economic effectiveness. Methods of evaluation can combine examinations with summing up work and appraisal of achievements. After assessment, the examinees should be given awards according to the standards they measure up to and be promoted by the academic committee and given corresponding technical titles.

It is this writer's view that as long as the leaders at different levels give full attention to the management of agricultural, scientific and technical personnel and take feasible measures, the ranks of agricultural scientists and technicians is sure to grow in strength and numbers.

CRITERIA FOR ANALYZING SUITABILITY FOR AGRICULTURAL MECHANIZATION

Tianjin KEXUEXUE [SCIENOLOGY] in Chinese No 5, 20 Oct 81 pp 36-38

[Article by Liu Tianfu [0491 1131 4395]: Institute of Technology Economics, Chinese Academy of Social Sciences: "Fifteen Key Elements in the Economic Analysis of Agricultural Mechanization Techniques"]

[Text] This article explores preliminarily the economic analysis of the agricultural mechanization techniques, bring about 15 key elements that should be given attention. These 15 elements are: standpoint, point of view, methods, demands, capabilities, profitability, time, place, circumstances, objectives, standards, comprehensiveness, focus, steps, and measures.

By so-called standpoint is meant that it is necessary to proceed from the angle of China, or a given region, or a unit. In mechanization, we cannot copy mechanically the experiences of foreign countries or foreign areas, but rather we must analyze and digest them for our own use.

The so-called point of view is used here to mean a scientific point of view based on objective laws and scientific theories, such as the laws of natural change, the laws of growth and development of animals and plants, the laws of ecological balance, the basic economic laws of socialism, the laws of planned proportional development of the national economy, the laws of value, and in certain cases, the theory of gradually decreasing land rewards, and the theory of economic effectiveness. If these laws and theories are ignored, inevitably the objective laws will suffer penalties, resulting in numerous detours and losses in the march toward the mechanization of agriculture.

The so-called methods means the concrete methods of using the philosophical method of dialectic materialism to guide qualitative and quantitative analysis in economic analysis of the agricultural mechanization techniques.

The so-called demands means the requirement to develop direction, tasks, and objectives on the basis of the social needs in agricultural production. When objective realities require the use of a certain kind of agricultural machinery for their solution, or when it can be foreseen that a certain technical and economic benefits can be obtained, we should make a priority solution. For example, for large-scale reclamation of wasteland on the Sanjiang Plain in the Northeast, complete sets of farm machinery should be allocated, on the North China Plain, drying facilities are urgently needed during the three summer, rainy-season jobs [planting, harvesting and field management], and while the urgent need in mountainous and hilly regions is machinery for lifting water and for hauling. Only by carrying out these kinds of selective mechanization can we meet with objective needs.

So-called capabilities means that the utilization of a definite farm machinery must meet realistic technical and economic conditions. Five such conditions are included here as follows:

1. A source of funds. This includes contributions by communes and brigades, bank loans, and disbursements by the state.

2. Realistic industrial capability to provide farm machinery. This includes the variety, model, quantity, and quality of agricultural implements and spare parts, and technical services for farm machines.

3. Energy situation. If the degree of agricultural mechanization exceeds energy supply capabilities, the farm machine utilization rate must inevitably decline, resulting in the falling of the benefits from investing in farm machines. About half the diesel engines in China are used in agriculture, but China does not have a surplus of petroleum; therefore, in the process of China's farm mechanization, handling of the energy problem must certainly not be ignored.

4. Personnel training and scientific management conditions. If farm machines are to be used safely and with high efficiency, drivers and maintenance personnel will have to be trained. Without scientific management, the farm machine utilization rate cannot be very high. A representative survey shows 42 percent of drivers lacking certification. Under these conditions, equipment losses and other accidents are very high; therefore, training of personnel and scientific management are a major situation that cannot be overlooked.

5. Finding opportunities for surplus workforces. China's rural population is legion, and if this problem is not simultaneously solved, smooth development of agricultural mechanization cannot take place.

So-called profitability means that after using farm machines, peasant income should be greater than expenditures, or that costs of using farm machines will be lower than costs before machines were used, or that use of farm machines will enable peasants to earn more income.

So-called time, place, and circumstances means that the design, putting into production, and use of farm machinery must fit in with the time, the place, and the circumstances. Ours is a vast land in which natural conditions and agronomic requirements differ, therefore resulting in obviously different demands of farm machinery. In the meantime, because of the different socio-economic conditions, cultural conditions, technical and management levels in various areas, the farm mechanization process cannot be uniformly the same. There is no doubt that foreign machines and experiences cannot be blindly copied. Diligent study of different kinds of farm mechanization zones and the selection of the most advantageous course, plans, and methods must be done on the basis of an understanding of China's situation and the formulation of agricultural zones. For example, in one low-lying marshy place, machines for the draining of waterlogging are the principal problem to be solved, while in another area that is normally arid, machines for raising water and for spray irrigation should become the area's major stock of farm machinery. As another example, in places where people are numerous relative to land, or where a system of responsibility is practiced whereby production is contracted to households, large farm machines would become inappropriate, and small machines would have to be developed instead.

So-called comprehensiveness means that when analysis and evaluation of economic results of the use of farm machinery techniques, comprehensive analysis of other influencing factors are necessary. It is necessary both to consider value indicators and how to use these value indicators. It is necessary both to consider present and partial economic results and to consider long-term, overall economic results. At the time of comprehensive analysis, it is necessary to consider technical levels, communications and transportation conditions, management levels, changes in the management system, as well as the total labor expenses. Use of advanced machines also requires consideration of factors such as their role in stimulating technical innovation and the raising of the standards of techniques. In importing machinery, it is necessary to consider loan and interest payments, foreign trade price increase constant, and changes in international market prices. It is also necessary to consider the development of China's domestic industry and scientific research, the training of skilled people, and provisions for workforces.

So-called standards means the standards, criteria, and fixed quotas required in the use of farm machines. Standards generally means high output, superior quality, high efficiency, low consumption, safety, and benefits as reflected in the form of numerical values and in the major appraisal indicators for agricultural and economic techniques. Of course, relative comparison should be carried out to meet these standards, but absolute comparison against different fixed quota should also be employed to raise these standards. For example, the standards for putting farm machines on the market are to be based on the zoning plan and the allocation system of farm mechanization. These standards govern from the starting point of putting the farm machinery on the market, to the point where the market is saturated to between the critical margin of exceeding the economic needs, capabilities, and profitabilities and the suitability that is below the relative peak point.

In order to carry out selectively the course of mechanization, all jurisdictions will have to have specific standards. For example, the production brigades in the Northeast that have met the following standards can be "mechanized" first:

1. The average area of cultivated land for which the brigades workforce is responsible is more than 30 mu.

2. The natural resources of forestry, livestock, and fishery is above 5 mu per person in average; and income from industrial sideline occupations amounting to slightly more than 40 percent of total income.

3. Per capita earnings distributions of more than 150 yuan.

In addition, agricultural mechanization work must also give serious attention to study of quotas and conversion equivalents, substantially instituting an average amount of investment in farm mechanization per mu of cultivated land, and a fuel consumption quota per hour per horsepower. Study must be given on how to convert to unified units of measurement of manpower, machines, and draft animals, and on how to convert farm products, diesel fuel, steel, and electric power to comparable thermal units.

So-called objectives means the goals sought through use of farm machines. Mechanization is only a means whose immediate objective is to solve first what is the most needed for the development of agricultural production, what is the most obvious for increasing production and earnings, and what is the most effective in heightening the labor productivity rate, reducing the intensivity of labor, and in improving the labor conditions so as to achieve best economic benefits. The ultimate objective of mechanization is to satisfy society's ever increasing need for farm products and to steadily improve people's living standards. The standards by which the objectives are set should be the commodity rates for farm products, contract completion rate for exchanges of commodities, per capita consumption of various farm products, how many members of the non-agricultural population are supported by the grain produced by each member of the agricultural workforce, average amount of consumption grain per capita in rural areas, per capita distribution of earnings, and gross value of national production per capita.

So-called focus means the focus of farm machine placement in production and use. In regional terms, the focus should be on selection of places and units in which needs are most urgent, potential for increases in yields greatest, conditions for placement in production quite good, and technical and economic benefits quite good. An example is the Songnen Plain where soil is fertile and land plentiful relative to population, each member of the farming population farming 23 mu of land, or 6.2 times the national norm, but where yields average only slightly more than 250 jin per mu, where machine power averages only 0.036 horsepower per mu, and where investment required for farm mechanization averages only between 30 and 50 yuan. By contrast, in the South Jiangsu region, each member of the workforce farms an average of less than 3 mu; yields average about 1,000 jin per mu, and investment required for farm mechanization would amount to more than 200 yuan per mu. This shows that the focal point for placement of farm machinery should be in the northeast, while in the South Jiangsu region only after industrial sideline occupations and economic diversification have developed further to the point where they meet farm machinery placement standards and suitable machinery is available should there be a change in the focus for placement.

So-called steps means having a choice and proceeding in stages in the use of farm machines. Because of limitations posed by various objective factors, and because various conditions differ, we should start from certain major links, and gradually fill in the gaps to complete the whole process, proceeding from initial mechanization to substantial mechanization, and finally to total mechanization. This requires that farm mechanization be done selectively and in stages. Consequently, this requires that we proceed on the basis of actual conditions, and step by step do a good job in farm mechanization plan appropriate to local conditions. Today, manpower used nationally averages 0.02 horsepower per mu of cultivated land; draft animal power averages 0.028 horsepower, machines average 0.022 horsepower, and electricity averages 0.256 horsepower. Looked at in terms of the rural energy resource structure, the ratio of man and animal power is still rather large. Therefore, beginning now and for a fairly long time to come, a situation will exist nationally in which manpower, semi-mechanization and mechanization co-exist, some areas being substantially mechanized and various agricultural production bases being totally mechanized. However, other different areas can carry out mechanization in several stages: Places with large populations relative to land should first lean toward projects such as drainage and irrigation, long distance hauling, drying, and plant protection, to develop guaranteed high-yield and stable output in which achievement by manpower is difficult but by machines is comparatively profitable, then gradually creating conditions for the realization of complete mechanization. In places where population is scant relative to land, emphasis will go first to increasing the labor productivity rate, to assuring that work gets done during the farming seasons, and to selecting projects that can release the most manpower and to achieve breakthroughs. We must carry out, step by step, basic mechanization to benefit production on an in-depth and broad scale.

So-called measures means the economic policy on farm mechanization techniques, production guidelines, and the way the structure of production forces is formed and other guaranty measures. There are questions regarding this to be discussed. In energy policy, for instance, should diesel engines be the main source of power, or should coal, electricity, petroleum, wind, sunlight, water, and gas be developed simultaneously as sources of power? Should farm machines be mostly imported from abroad, or should nationally produced farm machinery predominate? Should mostly high horsepower models of farm machines be developed, or should there be a combination of large, medium, and small models? Should there be mechanization for mechanizations sake with the task of mechanization being completed within a limited period of time, or should there be specialized guidance, concrete analysis, and implementation approach that provides choices? Should there be state-owned tractor stations in the management system? In farm machine pricing policy, how should the state subsidize farm machinery products? Other questions are policies on farm machine repairs and tax exemptions, tractor transport on highways, the domestic exchange rate and lowering of prices for commercial materials supply and importation of farm machinery in foreign trade. Other questions are: wise investment by the technicians and economists engaging in agricultural mechanization, whether the placement and the distribution of farm machines should set a time period for investment recovery, the quota and the number of years imposed on the use of the farm machines, as well as guidelines and policies on financial allocation of specific projects and bank loans. All these matters will have a very large bearing on how farm mechanization develops, the speed of its development, and the extent of its economic benefits. In addition, the improvement of the management system is also very important. For example, policy measures adopted by Wuxi County which called for commune-run grain stations to centralize the drying of paddy not only solved the problem of individual production teams not being able to afford drying machines, the lack of full use of such machines, and the lack of economy in use of such machines, but also the serious problem of rotting grain harvested in summer. All these things bear on analysis of the economic effectiveness of using farm machines.

The interrelationship of the 15 elements in the economic analysis of farm mechanization techniques shows the following: 1. Demands, capabilities, and profitability are the core and major components in the economic study and analysis of the techniques used for farm mechanization. 2. Objectives have to be divided into those that are ultimate and those that are immediate, both of them determining the direction and goals of the application of farm mechanization. 3. In terms of production and social demand, these 15 key elements are only potential requirements. Only when demands, capabilities, and profitability are considered together can these elements be realistically implemented in farm mechanization. 4. In the element of capabilities, there is a relationship among various economic conditions that are mutually conducive and restrictive. 5. Measures and policies are the guarantee in which techniques, principles and the actual implementation can be carried out. 6. Stance, point of view and methods are the guiding thoughts in farm mechanization techniques and economics. 7. Time, place, and circumstances are concrete employment of the dialectic method.

In summary, when we analyze and appraise the application of technique and economy in farm machinery, we should grasp and apply these 15 key elements, looking at the zoning charts, the timetables, and the classification of quota system so as to thoroughly comprehend the overall situation, synthesize research, and analyze and compare in our attempt to ascertain a more accurate economic assessment and conclusions.

1981 AGRICULTURAL, SIDELINE PROCUREMENT PLAN OVERFULFILLED

Fuzhou FUJIAN RIBAO in Chinese 19 Jan 82 p 3

[Article from Xinhuashe: "1981 National Agricultural Sideline Products Procurement Exceeded Plan. Procurement Valued at a Total of More Than 23.5 Billion Yuan, a 7 Percent Increase Over 1980, a Record Year Over the Past Several Years"]

[Text] 1981 was China's best year during the past several years for agricultural sideline production procurement. Statistics from the National Supply and Marketing Cooperative Administration show the value of national agricultural sideline production procurement during the year to have totaled 23.54 billion yuan, exceeding plan for the year and showing a 7 percent increase over 1980. The provinces and autonomous regions of Guizhou, Yunnan, Xinjiang, Liaoning, Jiangsu, Shandong, and Jilin in which the extent of increase was substantial, had an increase ranging from 10 to 34 percent.

Agricultural sideline production during 1981 was characterized by pronounced increases in the amount of procurement of raw materials for some major light and textile industries. This helped to ease the tense situation of a supply shortage and to increase warehouse storage of some raw materials. As of the end of December 1981, cotton procurement throughout the country amounted to 52.43 million dan, a more than 4 million dan greater procurement than in 1980 for an 11 percent overfulfillment of plan. Procurement of an additional approximately 3 million dan is anticipated. Jute and amberi hemp procurement has already amounted to 10.38 million dan, exceeding plan by 30 percent. More than 23 million dan of flue-cured tobacco has been procured, exceeding plan by 36 percent. Raw materials for the light and textile industries including ramie, sun-cured tobacco, pure goat hair, sheepskin, and silkworm cocoons also overfulfilled procurement plans.

Another characteristic of last year's agricultural sideline production procurement was the attention given to overcoming the state of turmoil in procurement work and improvement in the planning of procurement. During the past 2 years, tea output annually increased by 400,000 to 500,000 dan, but because of the numerous channels through which it was procured, state procurement plans were not well fulfilled for a time. Last year planning and management were improved and the state purchased 5.43 million dan, an all-time high. Procurement plans for dry products and fruits were also fulfilled rather well. Apple procurement was 360,000 tons more than in 1980, and orange procurement was greater by 70,000 tons. Red dates, black wood fungus, and day lily procurement also overfulfilled plan.

Some problems still exist in agricultural sideline production procurement, however, the major ones being some scarcity of commodity products, and people from non-producing areas going into producing areas where they purchase at inflated prices and capture the sources of supply, thereby impairing fulfillment of procurement plans. Because profits are small and a lot of work required for some third category agricultural sideline products, supply and marketing units are not very enthusiastic about handling them, and the quantity procured has declined. These problems have aroused the attention of departments concerned, and they will be gradually solved in the course of agricultural sideline product procurement this year.

BRIEFS

GROSS VALUE OF AGRICULTURAL OUTPUT UP-- China's restructuring of the internal structures of agriculture and of agricultural crop patterns has brought fine results. Despite frequent natural disasters during the past 3 years, with increases and decreases in grain production, gross value of agricultural output has increased at a rate of 5 percent each year. Comparison of 1981 with 1978 shows a general increase of more than 15 percent. Data reported by individual provinces shows that the area sown to grain in 1981 was more than 100 million mu, slightly less than that of 1978, yet the increase in grain output was more than 30 billion jin, making it the second highest year for grain output since the founding of the People's Republic. In 1981, cotton, oil-bearing crops, and sugar-bearing crops increased by 31, 80, and 32 percent respectively as compared with 1978. Mulberry silkworm cocoons, tea, and flue-cured tobacco increased by 44, 21, and 12 percent respectively. [Text] [Taiyuan SHANXI NONGMIN in Chinese 12 Jan 82 p 3] 9432

NATIONAL LOANS TO AGRICULTURE INCREASED IN 1981

Beijing ZHONGGUO CAIMO BAO in Chinese 30 Jan 82 p 1

[Article: "Meeting the Needs of the Implementing of Systems of Production Responsibility and the Comprehensive Development of Agricultural Sideline Production, National Agricultural Banking Departments Last Year Loaned Over 33.2 Billion Yuan; Nearly 90 Percent of the Loans Were Repaid, Due to Good Economic Results"]

[Text] Meeting the nee to implement systems of production responsibility and to comprehensively develop agricultural sideline production, the nation's banking departments in 1981 issued loans to state agriculture, commune agriculture, and brigade agriculture and to commune enterprises and commune members totaling 33.28 billion yuan, an increase of 3.87 billion yuan over the previous year, and effectively supported food and economic crops and the development of a diversified economy.

Last year, the nation's agricultural banks and credit unions issued loans worth over 16 billion yuan to commune and brigade collectives, an increase of 9 percent over the previous year. Banks and credit unions vigorously supported the comprehensive development of agriculture, forestry, animal husbandry, sideline production, and fisheries. According to provincial and municipal ststistics, the proportion of diversified economy loans among agricultural loans to communes and brigades has increased from 30 percent to about 50 percent. The nation's credit unions issued a total of 3.3 billion yuan in loans to commune members--an increase of 2.1 billion yuan over the previous year, or a 1.75-fold increase.

Agricultural banks and credit unions have actively supported the development of commune and brigade enterprises in readjustment and reorganization. Last year the nation's total loans to communes and brigades was 13.9 billion yuan--1.6 billion yuan more than during the previous year, for an increase of 13 percent--mainly to support the developing of marketable consumer goods and medium and small agricultural tool production.

To supply the rapid development of state-run agriculture, agricultural banks last year loaned state-run agricultural enterprises 3.3 billion yuan, an increase of .93 billion yuan or 39 percent over the previous year. The large increase in loans to state-run agriculture was due to increases in state farm-operated industrial sideline production, expansion of the scope of loans, pilot programs in medium- and short-term loans for equipment and support for flood relief and restoration and expansion of production of state farms in Heilongjiang and other provinces.

Owing to the good economic results of the loans, the returns last year were also good. Last year a total of 29.6 billion yuan in agricultural loans was repaid, equal to 89 percent of the loans made.

AGRICULTURAL DEVELOPMENT POLICY DISCUSSED

Beijing ZHONGGUO CAIMAO BAO in Chinese 2 Feb 82 p 3

[Article by Huang Daoxiz [7806 6670 7209]: "Rely on Policy and Science To Accelerate the Development of Agriculture"]

[Text] When Premier Zhao Ziyang proposed the 10 principles for future economic construction in his government work report to the Fourth Session of the Fifth National People's Congress, he mentioned first of all: "Rely on policy and science to speed up the development of agriculture." He pointed out the path of China's agricultural development and explained the ways and means of this path. Below we discuss this principle from three perspectives.

1. The central issue is improvement of agricultural economic results.

The accomplishments of China's socialist agriculture in the past 32 years have been very great. However, because we have taken a tortuous path, agricultural labor productivity is now very low. In guiding ideology in particular, we suffered in the past from the mistaken influence of the left and did not do things strictly according to objective and natural laws, did not adequately mobilize the initiative of the peasants to develop production and maintain the socialist path, and did not undertake a diversified and comprehensively developed agriculture. In addition, the failure to consider cost in agricultural production, profit and loss in management, and value in labor resulted in an extraordinary waste of manpower, material, financing, and natural resources, so that the economic results in agriculture were very low. These defects have severely hindered the development of the superiority of the socialist system and the accelerated development of the agricultural economy. In carrying out the Party Central Committee's series of principles and policies over the past 3 years, a great deal fo work has been done, the initiative of the peasants has been mobilized, and there have been evident improvements in production and in the income of the peasants, but the defects mentioned above have still not been completely overcome. In particular, improving the economic results in agriculture is a problem that urgently awaits resolution.

Improving the economic results of agriculture requires the establishment of the idea of a comprehensive development of agriculture. We must conscientiously implement the policy of "actively diversifying economically without giving up food-grain production," and correctly handle the several relationships among food crops, between food crops and economic crops, between agriculture, forestry, animal husbandry, sideline production, and fisheries, and between agriculture and commerce, so that all rural construction will be able to develop in concert. China has over 1 billion mu of land under cultivation, over 4 billion mu of grassland, and several billion mu of mountainous and marginal land suitable for forestry and grazing. China has vast shallow waters and coastal waters. In the villages, China has very adequate labor resources, and if only we would firmly establish the idea of comprehensive development under unified planning and management, suiting measures to local conditions, and, according to the different natural conditions of different areas, fully develop the superiority of the natural resources, technical forces, and human resources of each area, concentrating on developing what is suitable for development, we would be able to maximize advantages and minimize shortcomings and achieve greater economic results with less investment. In line with the demand for the comprehensive development of agriculture, forestry, animal husbandry, sideline production, and fisheries, we should tap new sources of production and advance in depth and breadth, and in this way China's agriculture will achieve even greater overall economic results.

2. Rely on policy to develop agriculture.

Since 1979 we have been smashing the bonds of "leftist" thinking, carefully stressing the links of establishing and making viable various kinds of systems of responsibility in agricultural production, and diversifying economically as suits local conditions, and we have begun to readjust agricultural policy and rural production relations and to guarantee the autonomy of production brigades. In this way we not only have overcome the faults of blind commandism in production, the egalitarianism in allocations, and the stifling overcentralization which exists in collective economic management, but through better organization of labor and methods of calculating pay we have brought about a readjustment of rural collective managerial methods and productive relations and have mobilized the productive initiative of the peasants. In addition, the Party Central Committee and State Council adopted a series of measures and policies to develop the rural economy to produce a generally good situation in agriculture which it has not had before. The principal economic forms in China's villages now are collective economies of different scale and different degrees of socialization. Concurrent with this are state farms and commune member family economies which supplement the socialist economy. Such diversified socialist economic structures are good for promoting more rapid development of agricultural productive forces and fully developing the superiority of the socialist system.

Systems of production responsibility are now being universally established in rural areas. We should adopt a positive and serious attitude and unrelentingly do a good job of improving and perfecting the system of production responsibility so as to gradually improve various forms of the production responsibility systems, including agriculture, forestry, animal husbandry, fisheries, industry, and commerce. In stabilizing and improving the system of production responsibility, we must protect the principal position of the people's communes, brigades and production teams, and protect and utilize well the collective means of production and public property that we already have. In particular, we must maintain collective ownership of land, and pay careful attention to protecting land that is under cultivation and arable land that is being rationally used. Any arable land, wasteland, grassland, hilly land, or underwaterland which belongs to a collective but which is not under unified planning and management by the collective cannot unilaterally be occupied and used by any unit or individual. Rights to private plots and hills distributed to commune members by the collective belong to the collective, as does residential land. Every effort must be made to make land contracts reasonable and to strictly prohibit the use of contracted land for building houses or graves or removing soil. Land contracted to a commune member cannot be bought or sold, rented or transferred, or allowed to lie fallow. Otherwise, the collective has the right to reclaim it. The rural basic political rights organizations should be further reorganized and strengthened, and their positive functions should be fully developed. All our rural cadres and commune members must clearly understand that the ownership of China's basic means of production, rural socialist collectivized roads and lands, is unchangeable and that the system of implementation of production responsibility in the agricultural collective economy is unchangeable. The aim of establishing and mkaing healthy the system of production responsibility in agriculture is to improve the rural socialist economic system so as to make the collective economy stronger and better developed.

3. Research in the extension of agricultural science and technology must occupy in an important position.

Science is a latent productive force. Once applicable agricultural science and technology are researched and applied to production, the economic results are very evident. For example, in 1980 the area planted in hybrid paddy rice was expanded to 79 million mu nationally and generally produced over 100 jin more per mu than common paddy rice plantings. This is a clear demonstration of the enormous power of the intellectual investment in science and technology in expanding production. After the system of production responsibility was implemented in the general rural areas, a high tide of "study science, apply science" began to rise.

At present we must combine closely the short-range and long-range needs of agricultural, forestry, animal husbandry, sideline and fisheries production, and formulate a group of sicentific research projects, such as developing and disseminating superior strains, improving cropping systems, improving crop distribution, reforming chemical fertilizer composition, carrying out the rational application of fertilizer, producing effective agricultural chemicals with low toxicity, practicing the selective use of agricultural machinery, etc. In addition, attention should be paid to scientific and technological guidance of the diversified economy and commune members' sideline production. These are all needed by long-range and short-range agricultural production; there should be a planned science and technology assault and a vigorous dissemination to suit local conditions. Agricultural scientific research, educational, and dissemination organs at all levels should work together and produce results as quickly as possible. We should combine China's superior traditions in intensive cultivation and the result of modern scientific and technological research; strive for low investment, low consumption, and high results; and, while protecting the ecological balance, strive for an increase in the agricultural commodities we need from the natural world.

BRIEFS

ZHANG PINGHUA AT AWARDS MEETING--Beijing, 3 Apr (XINHUA)--The State Agricultural Commission and the State Scientific and Technological Commission jointly held a meeting in Beijing today to present certificates of merit, award certificates and cash awards to units and individuals outstanding in popularizing major results of agricultural scientific research. Awards were presented to 1,248 units and 924 individuals. Vice Chairman Tong Dalin of the State Scientific and Technological Commission presided over the meeting at which Vice Chairman He Kang of the State Agricultural Commission read out the "circular of awarding those who have popularized 224 agricultural scientific and technological results" and the major agricultural scientific and technological results popularized by the award winners. First Vice Chairman Zhang Pinghua of the State Agricultural Commission presented certificates of merit, award certificates and cash awards to units and individuals and made a speech. He stressed: It is necessary to make continuous efforts to eliminate the "leftist" influence and the influence of small producers' parochial ideas and of the force of habit; to thoroughly change the still existing view of looking down on agricultural science and technology, especially on the work of popularizing agricultural science and technology; and to conscientiously give priority to agricultural scientific and technological research and agricultural education and to popularizing results in this regard. INCREASED GRANARY CONSTRUCTION REPORTED

Fuzhou FUJIAN RIBAO in Chinese 19 Jan 82 p 1

[Article by Zhou Jing [0719 7234] and Guo Xun'an [6753 0534 1344]: "Jianyang Prefecture Completes Construction of 20 Granaries"]

[Text] Jianyang Prefecture has newly constructed 20 granaries to increase capacity by 25.5 million jin.

Jianyang Prefecture has had bumper grain harvests for the past several years, and peasant grain sales have increased year by year to the point where a glut of grain in granaries has regularly occurred. Grain units have not been able to make purchases, causing a situation wherein peasants have found it difficult to sell grain. This problem aroused the serious attention of provincial units concerned and of prefecture leaders, who allocated special funds to grain units at all echelons for the building of granaries. Total granary capacity planned for construction in the prefecture is 120 million jin. Granary construction begun in 1981 was threefold that of 1980. Construction has been completed of a granary storage capacity of 25.5 million jin, and 80 percent of the construction has been completed on an additional 25.5 million jin of granary storage capacity. The additional construction of these granaries will help solve a storage problem that has been a key one in peasant difficulties in selling grain. Pucheng County, which is known as the granary of northern Fujian, now has 10 warehouses completed for use, and another 8 warehouses have been built and are awaiting inspection and acceptance before being turned over for use.

SIX PREFECTURES MEET GRAIN PROCUREMENT QUOTAS

Fuzhou FUJIAN RIBAO in Chinese 19 Jan 82 p 1

[Article compiled from drafts sent in by Huang Wende [7806 2429 1795], Chen Yisong [7115 6318 2646], and Fang Zhenhua [2455 2182 5478], News Report Unit, Longqi Prefecture Grain Bureau: "Six Prefectures Fulfill Grain Procurement Quotas. More Than 1,600 Households Sell 10,000 Jin of Grain. Broad Masses of Peasants Actively Support National Construction"]

[Text] In the wake of Xiamen City, the six prefectures of Longqi, Putian, Sanming, Ningde, Jianyang and Jinjiang fulfilled, one after another, their grain procurement quotas for the entire year.

The broad masses of commune members in these six prefectures fought against numerous natural disasters to win a bumper autumn grain harvest, making up in varying degrees losses sustained in the early crop, for an increase in total output for the year as a whole. Increase in output of autumn grain in Sanming and Jianyang prefectures was between 100 million and somewhat more than 200 million jin. Party and government leaders at all levels gave ideological education to commune members in "concurrent concern for the three" [the state, the collective, and individuals], and in "support to the three," guiding everybody in the establishment of a patriotic concept and a perspective in overall situations and increasing enthusiasm for selling procurement grain, and selling more excess grain. The 21 counties and municipalities in Sanming and Jianyang prefectures fulfilled their procurement quotas in a balanced way. In Longqi Prefecture, 17 communes sold more than 10 million jin of grain, and 72 production brigades made grain sales of more than 1 million jin. In Longhai County, the county with the most procurement grain in the province, commune members maintained their momentum of many years in eagerly selling grain, again fulfilling their procurement quotas for the entire year with 168.94 million jin. Nanjing and Fuding counties, which sustained flood disasters, devoted urgent efforts to early organization of the movement of autumn grain into granaries, and diligently balanced out abundance and scarcity, while at the same time fulfilling procurement quotas as usual. Every production brigade in Lixin Commune, Jianning County had a bumper autumn grain harvest, and every household increased output. The commune put more than 15 million jin of grain in storage in an 18 percent overfulfillment of procurement quotas.

In this prefecture, a steady stream of households has been selling 10,000 jin of grain. Incomplete statistics show that more than 1,617 households have sold

10,000 jin of grain, 22 of them having sold between 20,000 and more than 40,000 jin. In Longxi County, which had never had a household selling 10,000 jin of grain, 101 households have joined the ranks of households selling 10,000 jin of grain.

Analysis of grain quality purchased by grain units shows quality of grain entering granaries to be better than in former years. Grain of better than medium quality accounts for more than 80 percent of the total. Communes and brigades in Zhangpu County sold 18 million jin of autumn grain. Following winnowing and sifting, comparison of this grain with national grading standards at the time of storage showed 90 percent to meet better than medium grain standards.

OVERFULFILLMENT OF GRAIN PROCUREMENT TASKS DESPITE NATURAL DISASTERS REPORTED

Lanzhou GANSU RIBAO in Chinese 4 Jan 82 p 1

[Article by Cheng Wensheng [2052 2429 3932]: "Jiuquan Prefecture Overfulfilled 1981's Grain Procurement Task"]

[Text] Statistics from 30 December 1981 show that Jiuquan Prefecture has placed in granaries 211.89 million jin of grain; an 0.9 percent overfulfillment of grain procurement quota, thereby having completed state purchase tasks.

Last year Jiuquan Prefecture sustained diverse natural disasters, but thanks to the strenuous labor of the broad masses of cadres and commune members who took various rescue actions, the damage caused by the natural disasters was reduced. Following the grain harvest, prefecture and county leaders went into communes and brigades where, depending on the extent of plenty or want, they promptly readjusted tasks for communes and brigades that had been hard hit and where hardships were great. In a demonstration of no reduction in their contributions despite reduction in output, the broad masses of cadres and commune members diligently carried through the principle of concern for the three [the state, the collective, and individuals], and actively completed their tasks. Anxi County overfulfilled quota by 15.7 percent and completed its procurement task for the full year 16 days ahead of schedule, with each member of the farming population providing the state 617 jin of commodity grain, an all-time record. More than 80 percent of first and second grade wheat has been placed in granaries in Jinta County.

CORN GROWING IN MOUNTAIN REGIONS EXTOLLED

Lanzhou GANSU RIBAO in Chinese 10 Jan 82 p 1

[Article by Reporter Yang Chunchang [2799 2504 2490]: "Corn Yields of 785 Jin Per Mu From Mountain Drylands; Seven Peasant Households in Jishishan Produce Fruitful Results From Scientific Farming"]

[Text] A total of seven commune member households including that of Zhang Dengqing [1728 4098 3237] in Hejiacao Production Team, Guanjiachuan Commune, in Jishishan County organized the scientific farming of 18.67 mu of mountain dryland corn for yields averaging 785 jin per mu, creating a record yield from drylands in the mountain area for which they obtained a 2,800 yuan reward from the county government.

These seven households of commune members studied science and applied science. It was after the institution in 1980 of the contracting of work tasks to individual households, and after they saw that a county farm technician and cadre's family having had produced corn yields that averaged 216 jin more per mu, did the seven households of commune members decide to begin scientific farming. They took the initiative in seeking instruction from this farm technician cadre in the scientific principles of high corn yields, organized, and asked this farm technician cadre to guide them in running an experiment in high-yield farming. They also selected as the object of their experiment the major locally grown crop, corn. In the course of the experiment, they made sure to do the following: 1. rational rotation of crops; 2. use of superior varieties; 3. reasonably close planting; 4. scientific composting of manure and spreading of manure; 5. chemical treatment of seeds, disinfecting of soil, and removal of diseased plants.

Following autumn harvest, the output of the experimental corn fields of these seven households exceeded the yield per unit area single crop output standards for bumper harvest fields set by the county science committee and the county farm and livestock bureau. Commune member Zhang Denqing's 1 mu of corn produced 995 jin, and Zhang Fenglin's [1728 7364 2651] 5.5 mu of corn produced yields of 875 jin per mu, almost double the yields of surrounding fields. This made the masses realize the potential for increased yields from drylands in the mountain region and aroused mass enthusiasm for science.

BRIEFS

EFFORTS TO COMBAT SNOWFALL--Since mid-March the pastoral areas of Gannan Autonomous Prefecture have experienced heavy snowstorms and the temperature has dropped drastically. Snow measured as deep as 0.5 chi in some grasslands, bringing serious harm to animal husbandry production. To combat the effects of snowstorms, the Gannan Prefectural CCP Committee and government instructed departments concerned to organize three work groups of livestock breeding experts to go to various counties to investigate and help implement animal protection measures. Together with county leaders, these work group members earnestly studied and handled probelsm on deliverying additional fodder and medicine to disaster-stricken areas and dispatching veterinarians to assume responsibility for production teams and herds and organizing mobile medical teams to tend and protect animals, specially female animals, breeding stock and young animals. To ensure the survival of lambs, many livestock raisers braved strong winds and cold weather to graze their animals on the leeward or on grassland where snow was not as deep. Thanks to these feasible measures this prefecture had produced 400,000 young lambs by the end of March and the survival rate reached 90 percent. Presently, snowstorms are still occurring and disaster-combating work is still being carried out in the pastoral areas of Gannan Prefecture. INTELLECTUALS CREDITED WITH SOCIALLY, ECONOMICALLY USEFUL CONTRIBUTIONS

Beijing GUANGMING RIBAO in Chinese 21 Jan 82 p 1

[Article by Correspondent Yang Kaimin [2799 7030 3046]: "Jiangsu Province's Intelligentsia Play Major Role in Agricultural and Industrial Production. Implement Program of Scientific Study to Serve the National Economy. Jiangsu Provincial CCP Committee Convenes Symposium of Intellectuals in the Science, Technology, and Agricultural Education System to Greet New Year. Xu Jiatun [6079 1367 1470] Expresses Solicitude For and Extends Greetings to Scientific and Technical Workers"]

[Text] "During 1981 the intelligentsia played a major role in Jiangsu Province's increased agricultural and industrial production, and in the new progress made in science, culture, education, and athletics." These words were spoken by Jiangsu Provincial CCP Committee First Secretary Xu Jiatun on 19 January at a discussion meeting of intellectuals in the science education system convened by the Provincial CCP Committee to greet the new year.

During the past year, Jiangsu Province has made steady progress in industrial and agricultural production while in the midst of readjustment. Gross output value of agriculture in the province was 15.6 billion yuan, a 5 percent increase over the previous year for first place in the country. This included a 2.2 percent increase in grain, a 27 percent increase in cotton, a 68 percent increase in oil-bearing crops, and outputs of cocoons, tea, and aquatic products that surpassed the all-time highs. Gross output value of industry amounted to 49.39 billion yuan for second place in the country and a 7.9 percent increase over the previous year. This included a 15.3 percent increase in light industry.

In 1981 Jiangsu Province's intelligentsia put into effect a program of scientific research to serve the national economy. Selection of topics for research was linked closely to production realities for mutual cooperation in joint efforts thereby gaining numerous important accomplishments. In the course of the year, more than 270 items were applied and promoted in production, producing rather good social results and economic benefits. In the field of grain production, acting on the basis of production conditions in Jiangsu Province, farm technicians studied hybrid rice high-yield cultivation techniques. They planted an almost 10 million mu area that produced yields averaging more than 800 jin per mu, a 150 to 200 jin per mu increase over conventional varieties of intermediate rice. This was a major factor in the province's steady development of paddy rice production.

In the growing of cotton, promotion of seedlings cultivation in fields covered by plastic sheeting for later transplanting was done over 50 percent of the growing area, resulting in earlier and more numerous cotton bolls, and producing about 25 jin per mu more of ginned cotton than directly sown cotton, and breaking 10 million dan for 2 years. In the growing of rape, Ningyou No 7 superior variety bred by the Jiangsu Provincial Academy of Agricultural Sciences was promoted. This variety ripens early and produces high yields. Its oil content is high. As compared with the former single season variety, Ningyou No 7 variety ripens 5 to 7 days earlier; yields increase by an average of about 20 jin per mu; and oil content is also from 1.5 to 3 percent higher. In the industrial field, application and promotion of scientific and technical achievements played a positive role in improving quantity and quality of products, in reducing energy consumption, and in eliminating environmental pollution. Results from scientific and technical achievements were particularly striking in the case of the light and textile industries. The Wuxi Enzyme Manufacturing Plant, for instance, which together with the Microbiology Institute of the Chinese Academy of Sciences developed saccharogenic enzyme preparations, produces about half of the country's total output. This plays a major role in the development of the light, textile, and foodstuff industries.

Comrade Xu Jiatun expressed his solicitude and extended greetings to the scientists and technicians who have arduously struggled on the front line of scientific research. The symposium was held amidst enthusiasm and vigor in a lively atmosphere. The more than 200 delegates were filled with exultation. They competed with each other to talk, and they hailed the new achievements of the past year, and also made some constructive suggestions.

The symposium was presided over by Zheng Kang [6774 1660], director of Jiangsu Provincial Bureau of Science, Technology, and Agricultural Education. Also attending the meeting was the provincial governor, Hui Yuyu [1920 3188 1342].

NEW COTTON VARIETY COMPARED WITH OTHERS

Taiyuan SHANXI NONGMIN in Chinese 5 Jan 82 p 4

[Article by Hao Tuolan [6787 7474 5695], Provincial Academy of Agricultural Sciences: "High Yield Fine Quality Jinmian No 4 Cotton"]

[Text] Jinmian No 4 was bred by the Cotton Institute of the Provincial Academy of Agricultural Sciences. The hybrid progeny of Shanghai small-leaf cotton and Zhongmiansuo No 7 was used as the female parent, and Xuzhou 58 was used as the male parent in sexual hybridization to breed it. Experiments conducted during the 3 year period 1978, 1979, and 1980 have shown this variety to produce yields that are 25.4 percent greater than stock breed Daizi 16, for first position among 11 varieties.

Not only are yields from Jinmian No 4 high, but quality is good. Measurements and test spinning done by the Beijing Fiber Testing Institute show length of fibers of this variety to be 32.41 millimeters, 0.5 millimeters longer than Lumian No 1. Evaluation results from test spinning showed Jinmian No 4 to be class 1 grade 1, its quality meeting national textile standards.

Principal characteristics and properties of Jinmian No 4 are as follows: Fairly high pre-frost flowering. The 3 years of experiments showed pre-frost flowering to average 74.2 percent, 3.44 percent higher than for Daizi No 16. Pre-frost ginned cotton was 28.3 percent more than for Daizi No 16.

Jinmian No 4's resistance to cotton blight and verticillium wilt is the same as for Daizi 16 and Zhongmiansuo No 7, all of which are susceptible varieties. It is sensitive in reaction to water and fertilizer, and unbridled growth is to be guarded against during its late stage of growth.

This variety has a rather long period of growth and is suited for planting in the various cotton growing counties of Yuncheng Prefecture in the intermediate ripening cotton growing regions of Shanxi Province. It is a fine variety for use with plastic film covering the ground to obtain high cotton yields.

EVER GREATER EFFORTS TO COMBAT DROUGHT URGED

Taiyuan SHANXI RIBAO in Chinese 17 Jan 82 p 1

[Article: "Combat Drought to Protect the Wheat; Combat Drought to Prepare for Plowing, and Win a Bumper Harvest; Provincial Flood and Drought Prevention Command Telephone Conference Calls On All Jurisdictions to Take Action at Once"]

[Text] On the evening of 15 January, the Flood and Drought Prevention Command of the Provincial People's Government held a telephone conference in which it called upon all jurisdictions to act at once to combat drought to protect the wheat, prepare for plowing, and win a bumper harvest in agriculture this year. Deputy Provincial Governor Zhao Lizhi [6392 0500 0037] spoke at the conference.

The drought situation is now severe throughout the province. Snow and rain have been scant since last winter, a total of only 22 millimeters having fallen during the 3 month period October through December, an average 50 percent less than in most years. In many places summer drought was followed by fall drought, and fall drought was followed by winter drought. Because of the small amount of precipitation, a great drop in streams has occurred, and the province has more than 400 small reservoirs that have not filled with water. Winter was virtually snowless, so soil moisture conditions are inadequate, the soil being dry to a very great depth. This has already impaired normal growth of wheat. Furthermore, in many places dependent on ponds, water-retention wells, and streams for drinking water, getting water for people and animals has become difficult.

Meteorological department forecasts call for continued scant rainfall this spring, and drought will continue throughout the province.

In order to reap a bumper harvest this year, the telephone conference called upon all jurisdictions to take action at once in doing a solid job of combat against drought to protect the wheat and to prepare for plowing.

First, do a good job in thoroughly and conscientiously mobilizing peoples' thinking. Right now some comrades are blindly complacent, their comprehension of the seriousness of the drought and the importance of winning a bumper harvest insufficient. Though some have seen the advance of the drought, they are paralyzed because they rely on luck, hoping the heavens will send rain, and do not bend every effort to combat drought. Some have an inaccurate understanding of the system of responsibility, and have slackened their leadership over combat against drought. Some commune members fear the system of responsibility, and fear investment of funds and expenditure of labor; they do not actively combat drought and water the land. All jurisdictions should focus on these ideological problems and repeatedly make clear to cadres and commune members the seriousness of the increase in drought and the importance of combating drought to win a bumper harvest, so that the broad masses of cadres and people will understand the drought situation, have their confidence in combating drought strengthened, and adopt specific measures, firmly joining the struggle against drought.

Second, everything possible should be done to water more and water well. Reservoirs and ponds of all kinds should be used to store water, and temporary projects for water storage in streams should be given attention wherever conditions permit, so that every bit of water that can be stored will be stored. Communes and brigades receiving benefits should be organized at once to clean silt from ditches, put project structures in shape, and inspect and repair machine-powered pumping station facilities so as to be able to devote a larger number of water conservancy facilities to spring irrigation. In order to make the most of existing facilities to combat drought, it is particularly necessary that a system of responsibility for water management be instituted brigade by brigade, well by well, and station by station.

Third, broadly mobilize the masses to carry out harrowing of parched land to preserve water moisture. Three-fourths of the cultivated land in Shanxi Province is dryland requiring prompt rolling before thawing begins in early spring, and harrowing. In places where conditions permit, prompt action should be taken to promote combat against drought by dibbling seeds, seeding with a drill, and by doing concentrated spreading of manure so that spring planting will result in a full stand of seedling crops. In addition, provisions must be made for the planting of drought-resistant crops, a certain amount of seeds being collected and set aside in preparation against famine.

All locales are to strengthen leadership of drought prevention work. The combat against drought to protect the wheat, and to prepare for plowing covers a broad spectrum and requires solution to numerous problems. All locales should designate persons specifically responsible for these tasks; they should revitalize and strengthen organizations for combat against drought, and organize agricultural, water conservancy, electric power, trade, and public financial units for coordinated efforts to solve problems related to the use of electricity, fuel, and funds in fighting drought. Leaders at all levels in prefectures, counties and communes should improve their work styles and organize definite forces. Leaders should personally lead teams into the front line of combat against drought, make on-site investigation and study, supervise, and inspect, and make on-the-spot solution to problems to do a good job of combat against drought.

BRIEFS

GRAIN OUTPUT--Taiyuan, 16 Apr (XINHUA)--Dingxiang County in Shanxi reaped a total grain output of 200.6 million jin in 1981, up by 27.4 percent from 1978. At the same time, the county raised more than 76,000 head of hogs, 13,480 head of draught animals and 56,000 head of sheep and goats. ORG: Institute of Rice, Sichuan Provincial Academy of Agricultural Sciences

TITLE: "Why Can Strong Rice Seedlings With Many Tillers Increase the Yield?"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 2, 17 Feb 82 pp 3-4

ABSTRACT: In the southeastern region of Sichuan, the unit yield of rice of either the intermediate or the dual season systems is neither high nor stable. In either system, the previous crop is usually harvested late and transplanting is late as well. In the early period, the rice plant does not achieve sufficient growth; in the late period, it is easily affected by bad weather. In 1975, the author and colleagues began to study the technique of cultivating strong seedlings with many tillers. Since 1977, the technique has been extended in several million mu of paddies. The practice has proved that a yield increase of 5 percent for intermediate rice and 10-30 percent for dual season rice may be obtained with the technique. In the year 1980, 400 million jin of rice seeds were saved by the technique in Sichuan Province as a whole. The technique involves cultivating 3 types of seedlings: (1) Small seedlings grown in greenhouses to be used for transplanting early; (2) Ordinary strong seedlings suitable when the transplanting is just right; (3) Strong seedlings with many tillers suitable for transplanting wherever the wheat harvest is late. The weight of dry substance, the nitrogen and phosphorus contents, and the root system activity of the second and third types of seedlings are compared to show why the third type may be transplanted late and still produce an increase of yield.

TITLE: "Questions and Answers Concerning the Method of Promoting or Controlling According to the Leaf-age Indices of Wheat"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 2, 17 Feb 82 pp 7-10

ABSTRACT: Leaf-age is the term given to the time when a given number of leaves appear on the main stem of the wheat plant. The method means to carry out a given field management measure with the number of leaves on the plant as the guidance. These measures of promoting or controlling include mainly fertilizer application, irrigation, and withholding water. The number of leaves on the main stem may be counted directly. In case of numerous tillers, when the seedling has 3 leaves or 5 leaves, a red dot may be painted on the last leaf so that there will be no mistake in counting later on. Scientific basis of this leaf-age technique is analyzed in the following aspects: (1) The principle of coextension of leave-age and organs; (2) Correspondent relationship between leaf-age and spike evolvement; (3) Different fertilizer and water efficiency at a different leaf-age. Procedures and problems in the application of the leaf-age indices are introduced and discussed.

SOURCE: Beijing ZHONGGUO SHOUYI ZAZHI [CHINESE JOURNAL OF VETERINARY MEDICINE] in Chinese No 1, 22 Jan 82 pp 18-20

ABSTRACT: On 8 Feb 75, at the pig sty of the Jiutai County Bureau of Commerce, Jilin Province, a sow that was awaiting birth was found to suffer from diarrhea, a symptom very much like TGE. By 19 Feb, 119 of the 128 newborn piglets of the sty had come down with the disease, and 80 died. Of the 14 sows, 11 caught the disease. Cases of diarrhea had been reported in nearby communes, but none of the local horses, oxen, sheep, or chickens ever came down with the symptom. Disorders of the intestines, stomach, and kidney can be observed by the naked eye during dissection. Results of pathohistological examinations confirmed the diagnosis of TGE. Aside from treatment for dehydration, it appears that the condition of azotemia as indicated by the mainfestations of the dissected kidneys should be given special consideration. Reports on TGE by Underdahl Mebus, Healterman, E. O., Doyle, E. P., Tamoglia, T. W. Bohl, E. H., Thorosen, and Djurickowic, etc. are briefly reviewed.

TITLE: "A Survey of Swine Hematuria"

SOURCE: Beijing ZHONGGUO SHOUYI ZAZHI [CHINESE JOURNAL OF VETERINARY MEDICINE] in Chinese No 1, 22 Jan 82 pp 20-21

ABSTRACT: A survey disclosed that swine hematuria occurs mainly in the period from Apr to Oct, and most frequently from Jul to Sep, mostly in a dry spell, extremely rare in rainy days. It occurs mostly to thin pigs and in all cases, the pigs had been fed soybean leaves, turnip leaves, lima bean leaves, etc. that were damaged by aphids. When pigs have been fed 4-5 days with feed materials, 30 percent of which have been damaged by apids, the disease will occur, but it is usually mild. If more than 70 percent of the feed is damaged by aphids, severe cases of hematuria invariably occur in 2-3 days, and the pigs quickly die. Pathological surveys claimed that the disease is caused by aphid-containing feed. The results of dissection and feed analysis performed by the Research Institute of Animal Husbandry and Veterinary Medicine have produced a preliminary diagnosis of formic acid poison, however. The authors believe that as ants like aphid excrement, the aphid contaminated feed is also contaminated by ant excrement, which is, in reality, formic acid. Due to the fact that formic acid is easily dissolved in water, such feed is no longer poisonous after frequent rains.

TITLE: "The Abnormal Circulation of 1980 Which Caused Floods and Low Temperature in the Lower Reaches of Changjiang"

SOURCE: Shanghai ZIRAN ZAZHI [NATURE JOURNAL] in Chinese Vol 5 No 1, 1982 pp 25-29

ABSTRACT: Records of monthly averages are analyzed to study the month of Aug 80. The analysis led to the discovery of the fact that although the high pressure system of that month in the subtropics of the North Pacific was strong, its location was shifted much to the south of 30°N, the location of a normal year. Cold air masses came regularly from the East and the West going southward to cause the axis of the greatest westerlies to stay in the vicinity of 32.5°N instead of the vicinity of 42°N of a normal year. The north-south air currents converged in the region of the middle and lower reaches of Changjiang to shift the normal rainy region of the Huanghe southward. Rainstorms occurred easily of course in the region of the relatively large angle of intersection between the line of vortex concentration and the southerly inclined wind. This type of abnormal circulation pattern in East Asia is closely related to the circulation change in the Southern Hemisphere and the Atlantic Ocean.

SURVEY, APPRAISAL OF SURFACE WATER RESOURCES DISCUSSED

Hubei SHUILI SHUIDIAN JISHU [WATER CONSERVATION AND HYDROELECTRIC POWER TECHNOLOGY] in Chinese No 12, 20 Dec 81 pp 1, 53

[Article: "National Conference To Exchange Technical Experience in Surveying and Appraising Surface Water Resources Held in Wuhan"]

[Text] A national conference to exchange technical experience in surveying and appraising surface water resources was held in Wuhan city, Hubei Province, 20-28 October. This meeting was sponsored by the Hydrological Bureau of the Ministry of Water Conservancy commissioned by the Office of the National Agricultural Zoning Committee and the Water Resources Group. Delegates from the water conservancy (hydroelectric power) departments (bureaus) of the provinces, cities and autonomous regions, geological departments, river valley agencies, related schools, and scientific research and design units, totaling over 250 people, attended the conference. The conference received 167 papers and special topic reports.

Deputy Minister Chen Gengyi [7115 6342 0308] of the Water Conservancy Ministry delivered the opening remarks.

The mission of the conference was to exchange and summarize technical experience and some work experience in surveying and appraising surface water resources. The topics included: ground surface water, underground water, the relationship of ground surface water and underground water conversion, and water quality problems. Surveys and appraisal of water resources must answer four questions: first, how much water is available (including regional distribution, changes in time, quality standards, reliability); second, how much water is needed for socioeconomic development (present situation of water consumption of different types, near-term and long-range forecasts); third, what problems exist in the balance of supply and demand; fourth, what measures must be taken to solve existing problems in water resources. After 2 years of work, preliminary estimates show that the total average rainfall in our nation over many years is about 6 trillion cubic meters. The total average runoff in rivers over many years is 2.63 trillion cubic meters, including about 600 billion cubic meters of drainage of underground water from mountain and hilly regions. Separate calculations for the plains show that the comprehensive replenishment of underground water is 180 billion cubic meters. The total replenishment of underground water throughout the nation from the mountain regions and the plains is 780 billion cubic meters. Deducting the repeated amount of conversion between surface water and underground water, the total national water resource is about 2.7 trillion cubic meters. According to survey data of each province, city and autonomous region compiled in 1978-1979, the total annual consumption of water throughout the nation reached 450 billion cubic meters. Of this, about 400 billion cubic meters were used for irrigation in agriculture.

Activities of the conference included the presentation of reports to the general meetings, exchange of experience in small meetings, discussion of special topics and discussion sections in groups. At the general conference, 27 delegates read papers or delivered special topic reports. New topics included a preliminary appraisal of national water quality, estimates of icy river resources of the nation, and estimates of lake and inland sea resources of the nation. After the conference, small discussion groups were organized to discuss five topics: rainfall and evaporation, runoff and replenishment, conversion of the three states of water, water quality surveys and appraisal, and underground water. In addition, discussion groups were set up for each river valley region under cooperative management to discuss and arrange future work.

Several major problems discussed at the meeting were as follows:

1. The method of mathematical statistics and analysis is the fundamental method to study the characteristic values of rainfall and runoff and the pattern of time and space distribution. The key to improving the precision of frequency calculations so that the results are stable and reliable is: reliability of data, consistency of data and adequacy of representation of the series. Therefore, special emphasis must be placed on analysis and examination of basic data and analysis and proof of the adequacy of representation of the series.

How to correct the representation of short series stations positioned over large areas requires further study in the future.

2. Runoff and replenishment are calculated in order to solve the problems in the consistency of the series of data. The methods of calculating replenishment used by various localities include itemized survey and estimation, the study of rainfall and runoff trends, the study of the relationship between rainfall and runoff, the study of the model of runoff genesis, and the method of calculating differences in evaporation. The group discussion of specific topics resulted in the conclusion that surveying and analysis must be combined, many methods must be used, analysis must be comprehensive, and selection must be rational. As to the years of replenishment, group discussion of specific topics led to the conclusion that they should be the years with available actually measured runoff data since liberation. Replenishment should be calculated according to the amount of water lost or gained that year resulting from the affects of water conservancy projects on the upper reaches of the station conducting the measurements. Before liberation, water consumption was minimal, and that amount could generally be neglected in replenishment.

The problem of replenishment of runoff in plains, whether the northern plains or the southern waterway network, whether embankment regions or lake regions, still presents difficulty at present. Some units have proposed starting out by studying the evaporation of water surfaces and land surface evaporation to estimate replenishment. This is worth further exploration.

3. The isopleth graphs of rainfall, runoff and evaporation are a good method to study the patterns of the regional distribution of statistical parameters and the three elements in the balance of water resources, and to obtain the characteristic values of medium and small rivers which do not have available data. Drawing isopleth graphs requires not only that data gathered by a single station span a long period, and that the data are accurate, but also that the distribution of data is even and concurrent. It is difficult for these two conditions to exist simultaneously. Therefore, all data and concurrent data must be utilized to draw these two sets of isopleth graphs.

Topography affects the amount of rainfall. Yunnan and Guizhou Provinces have proposed the method of analyzing the relationship between altitude and rainfall. But the differences between the mountain regions are great, and one must be cautious when using this method.

In the northwestern interior, the high mountain regions and valleys of the Qinghai-Xizang and Yunnan-Guizhou Plateaus, the patterns of variation of the elements in the balance of water, rainfall, evaporation and runoff and the patterns of variation of the elements in the vertical climatic zones are distinct. We should pay attention to analyzing the effect of such factors as the altitude of the topography and the replenishment by melting ice and snow upon the elements in the balance of water.

The key to calculating evaporation is the accuracy of the data and the coefficient of conversion. Our nation's instruments for measuring evaporation are not uniform. At present, data on the conversion of large bodies of water are scarce. Everyone believes it is still better to first convert the data to the E_{601} type.

4. Appraisal of underground water resources can be accomplished by using the average measurement of the amount of water in plains to calculate the amount of replenishment. In ordinary mountain regions where the river valleys are closed and where subterranean flow is not large, separate calculations of underground runoff can be used. The results of appraisal by each region can be checked using the principle of balance of water quantities.

The correctness of the estimates of the various quantities of replenishment is determined by the basic amount of water available and such parameters as the amount of rainfall and the amount of water used for irrigation. The various hydrological and hydrogeological parameters such as the degree of water supply and the infiltration and replenishment coefficients must be selected according to the results of experiment and research at the locality.

To satisfy the demands of agricultural zoning, zoning for water conservancy and zoning of river valleys, the appraisal of underground water resources should be carried out according to natural units and hydrogeological units, and the results should be summarized for each river valley. Besides appraising the average amount of water over many years, we must also appraise the amount of water available under different percentages of guaranteed water supply.

5. Surface water and underground water alternate. Calculating them separately and appraising them separately are not only repetitious but also conflicting. To carry out an overall appraisal of water resources, we must study the alternating relationship among rainfall, surface water and underground water. In regions where underground water is exploited and utilized on a large scale, we must understand the amount of replenishment of underground water, and we must also understand the possible amount of reduction of ground surface water after massive extraction of underground water. The hydrogeological conditions in karst regions are complex. We should select a closed river valley for study and estimate the amounts of underground water and ground surface water simultaneously.

6. In surveying and appraising the quality of ground surface water, the criteria for appraisal are established by selecting the parameters according to the different uses of the water resources, requirements for water quality and the present situation in monitoring water quality in our nation. The method of appraisal presently used is simple and practical. Appraisal of large rivers, lakes and reservoirs using the average values of sections cannot reflect the true situation of pollution of the water quality. Pollution zones should be drawn up for appraisal.

The key problem in water quality appraisal is the quantity and quality of monitored data. The experience of combining the compilation of water quality data and water quality appraisal by the Hui River Committee and Shandong Province is worth popularizing.

Water quality and the quantity of water should be combined for appraisal so that the results are more rational.

7. The problem of water resources is often closely related to the uneven regional distribution of water resources and the variations within the year and between years. We should study the uneven distribution of water and soil resources, seasonal drought and floods, the alternating occurrence of years of continuous drought and floods, and we should analyze the problems that may occur as a result of industrial and agricultural production and problems in exploitation and utilization of water resources.

NEW DEVELOPMENTS IN HOG RAISING DISCUSSED

Hog Raising Under the New Conditions

Beijing ZHONGGUO NONGMIN BAO in Chinese 7 Feb 82 p 2

[Article by Su Feng [5685 6912], first secretary of the Tangshan Prefecture Chinese Communist Party Committee: "Developing Hog Raising Enterprises Under the New Conditions"]

[Text] The development of hog raising enterprises is a major topic which now concerns the peasants and the rural basic level cadres. I recently paid visits to Leting, Lulong, Qianan and other counties, communes and brigades to research this report, which presents some new conditions and issues for your study and investigation.

1. In the past, hog raising conditions in Tangshan Prefecture were relatively good. This was because at that time the method of "three hogs equals one laborer" was then in effect, and hog raising had predictable advantages. Take Leting County for example. Previously, when a 200 jin fat hog is sold to the state, the state will give 200 jin of feed grains, and in addition the work brigade would also give 33 work points for hog raising and about 28 points for manure collection, and also provide food grains at a price comparable to the state grain price. Income from the sale of one hog, with expenses deducted, came to about 87 yuan. The profit from three hogs figured out to the approximate equivalent of the income from one laborer. Therefore, commune members were at that time very much interested in hog raising. Statistics show that from January through September of 1981, the number of hogs that were raised was up 5 percent and the number in inventory was 2.6 percent higher than the same period in 1980.

2. The current tendency of a decline in hog production requires attention. Nonetheless, it must be observed that there is an increase in household hog raising. Because of certain adjustments which were made in carrying out the "dual contract" system and in hog raising policy there has been a decline in hog raising endeavors. We offer the following analysis. First, after pursuing the "dual contract" resonsibility system it became difficult to sustain collective hog raising. For example, in Lulong and Qianan counties, collective hog raising was reduced by 28,074 head. Second, in the past there was a relatively small ratio of hog raising by staff and worker dependents or by local households without contracts or with few contracts. Now, work points

for hog raising and for manure collection have been abolished, and there no longer is award sales of feed grain, so that raising one hog, deducting the expenses and investment, averages a profit of less than 10 yuan. They feel that such hog raising is "needless bother" and are unwilling to undertake it. For example, in 1980, the Qianan mining district cart-shaft brigade raised 2,800 hogs, mostly by the staff and worker dependents. This has now been reduced to 600 hogs. Third, there is an increase in the number of commune members raising hogs. The more we institute the responsibility system of linking remuneration to sales the more the commune members are willing to raise hogs and accumulate fertilizer. For example, in Qianan and Lulong counties the number of hogs raised by commune members is 31,214 head higher than in the past. Although the commune members are somewhat disgruntled about the decrease in state grain for hog raising, nonetheless as long as the improvements in hog raising policy are continually being made and when propaganda work has fully promoted hog raising, there then will be no major decreases in hog production.

3. The current problems in hog purchases do not stem from a shortage of hogs but rather are mainly caused by butchering and selling by individuals. In Leting, for example, prior to the Spring Festival, 150 jin and over hogs removed from inventory had reached 38,077 head, 3,563 more than at the same time in 1980. Why did the period of 1 October through 15 September of 1981 show throughout the whole district a 20 percent decline in daily purchase quantities compared to the pre-September period? The primary reason was an obvious increase in butchering and selling by individual commune members and increased slaughter by rural butchers. According to statistics from the Leting food products company prior to October 1981 the sale of a 200 jin grass-weight class-two hogs to the state produced revenues of 144.70 yuan. Yet, individual revenues were only about 5 yuan greater than from selling to the state, so there was considerably less individual butchering and selling. After October 1981, there was an additional 3 percent of both purchase tax and sales tax and the food company selling price increased 5 fen per jin, with a 5 fen per jin increase in the price of individually butchered and sold pork. Calculated together, individual butchering and selling of a gross-weight 200-jin hog then produced about 17 yuan more than state purchase of that hog. This was a great stimulus to individual butchering and selling. According to statistics dating from 5 December 1981 for the five major collective markets in Qianan County, food company sales amounted to only 21 percent of the total sale while individual butchering and selling accounted for 79 percent.

4. Following the development of the new conditions there must be continual improvement in certain concrete policies. Based on the principle of the triple consideration of state, collective and individual combines with the actual conditions in these areas, the study of a few possible methods must be done so as to mobilize peasant enthusiasm for hog raising and to guarantee the fulfillment of the purchasing tasks. For example, to guide and encourage commune members to properly manage their private plots so to provide the feed grain necessary for raising hogs, which will develop household hog raising and broaden the hog resources. By signing contracts of assigned procurement, we can promote the fulfillment of the purchase plan. We must not check individual butchering and sales, but we can only permit them under the premise of fulfilling the task of state purchases and collecting adequate tax receipts.

Brigades which are carrying out their responsibilities should institute the methods by which the base for fertilizer investment is established and the adjustment of the deficiencies and surplus can be carried out, as this will solve the problem of fertilizer accumulation for those staff and worker families which raise hogs. We must strengthen market management to put an end to the problem of tax avoidance and tax theft by meat markets. We should also point out that hogs classified as lean meat also show the greatest weight gains after reaching 150 jin, and not providing additional award sales of grain for hogs over 131 jin is not beneficial for the development of the lean meat class of hogs. These problems require further study and investigation in the process of implementation in order to promote hog raising development in our area.

Hog Raising Directive Implemented

Beijing ZHONGGUO NONGMIN BAO in Chinese 7 Feb 82 p 2

[Article: "Four Provinces Thoroughly Implement the State Council Hog Raising Directive"]

[Text] After the State Council sent down the directive on hog raising many provinces, municipalities and autonomous areas implemented it with stepped-up activities. Some provinces have already taken effective measures which have begun to produce results.

In Guizhou Province, in addition to insisting on the original state and collective award sales policy, a regulation was passed stipulating that for each fat hog there would be an allocation of one portion of foraging ground, two portions for each sow, an additional 60 jin of state award sales of grain for each sow and 8 jin for each live piglet born. For each three head of fat hogs turned over to the state by commune members, each household is allocated 500 jin of feed grain by the state.

Zhejiang Province requested that "dual contract" production teams assign both the feed grains and foraging grounds as well as the responsibility for the sale of live hogs either to the households or else keep the feed grain as a unit and award it to the families who sell hogs to the state. For both collectives and individuals, for each fat hog sold to the state there is an additional bonus of 10 industrial goods coupons for commodity items that are in critical demand such as bicycles and sewing machines. A system of assigned hog raising was instituted, implemented by either pig farms or households which raised pigs.

The Hubei Provincial Party Committee decided that each year it would exchange 10,000 dun of urea for oil cakes to make compound feed and improve the feed grain remuneration. For each jin of the gross weight in excess of the portions sold there is a bonus of one jin of unprocessed food grains.

In Hunan Province the September 1981 figure for live hogs in inventory shows a 10 percent decrease compared to that of the same period in 1980. Consequently, the provincial party committee issued a document strongly urging the departments concerned to become closely involved. According to yearend statistics from six prefectures including Anyang, the decline rate of the live hogs in inventory was stabilized at about 0.5 percent.

MANAGEMENT PROBLEMS IN ANIMAL HUSBANDRY DETAILED

Beijing NONGYE JINGJI WENTI [PROBLEMS OF AGRICULTURAL ECONOMICS] in Chinese No 12, 23 Dec 81 pp 19 - 23

[Article: "Summary of the Third National Conference on Economic Theories of Animal Husbandry (Part II). Part I published in JPRS 80042, 5 February 1982, No 188 of this series, pp 16 - 23]

[Text] III Production and Circulation Problems

Today a pile of problems exists in the circulation field. There is still quite a bit of leftist rigamarole around, and things that go against objective laws are also fairly numerous. These problems have hurt production and consumption, and unless they are promptly settled, there will be a great deal of future trouble. As some leadership comrades in the Central Committee have said, a bumper harvest can turn into a bumper disaster.

Sufficient serious attention must be directed to the position and role of commodity circulation of livestock products, both viewing seriously and studying production, and viewing seriously and studying circulation. A large body of facts has demonstrated that sole attention to production and no attention to circulation makes it difficult to do a good job in production, and often, because circulation exerts a drag on production, the more hurry the less speed.

Everyone is aware that an extremely important problem in the commodity circulation of livestock products is how to arrive at a correct price for livestock product..

Comrades have said that following the Third Plenary Session [of the 11th Party Central Committee], when the state made planned increases in procurement prices paid for some livestock products and shortened the price scissors, the peasants derived material benefits, which raised their enthusiasm for livestock production and advanced development of livestock industry production to bring about a preliminary change in the situation of shortage in commodity in circulation of livestock products.

However, some problems still remain in prices of livestock products today. 1. Some prices for livestock products continue overly low, as is the case with beef. for example. For a long time the state has set procurement prices paid for beef on a general standard for old and decrepit cattle, the procurement price averaging 0.40 yuan per shijin, which is lower by more than 30 percent than the average actual feeding cost of 0.60 yuan. In some parts of Nei Monggol, sale of a beef animal of about 500 jin live weight entails a loss of more than 200 yuan, and a similar situation exists in the case of other domestic animal and poultry products such as cowhide and honey. 2. Price parities between industrial and livestock products are not fair. For example, a milking machine costs more than 3,000 yuan, meaning that herdsmen would have to sell between 70 and 80 head of cattle to be able to buy one. For a shearing machine, herdsmen would have to sell between 650 and 700 head of sheep. Procurement price paid for a cowhide averages about 20 yuan, and between four and five pairs of boots can be made from the hide. Figuring a value of 40 yuan per pair, their total value would be 160 to 200 yuan, a four to five fold difference in cost price of raw material. Herdsmen in Xinjiang say, "it is better to ride a cow than to wear a pair of boots." 3. Parity prices among farm and livestock goods and among livestock goods are not fair. The price for superfine Xinjiang wool is 16 percent lower than the price for long cotton. In Nei Monggol, the procurement prices paid for fine wool and semi-fine wool are identical, but only about 5 kilograms per year of fine wool is obtained from a fine wool sheep, while only about 2.5 kilograms per year of semi-fine wool is obtained from a semi-fine wool sheep; thus the income from raising one semi-fine wool sheep is between 5 and 10 yuan less than from raising one fine wool sheep. Consequently, the masses and production units do not want to raise semi-fine wool sheep, so development of semi-fine wool sheep is slow and unable to satisfy national needs. Every year more than 5,000 tons of semi-fine wool has to be imported at a cost in foreign exchange of more than $20 million. 4. The practice still exists whereby quality is deprecated in order to force down the price to be paid, whereby dressed weight is estimated by looking at animals, and whereby grade of meat is lowered in order to lower price to be paid. State Council document number 26 issued in 1979 clearly stated that when buying cattle, "each head must be weighed, and a price set on the basis of quality, with no forcing down of grade in order to lower the price to be paid, and no looking at herds and estimating a price to be paid." However, as of today this problem still has not been solved.

In some places, the masses are very dissatisfied about the difficulties in selling hogs, and this subject has become a major topics for discussion by party representative assemblies and people's representative assemblies. Live hog production has become a burden. What is the reason for difficulties in selling hogs? One view holds that the essence of the difficulty in selling hogs lies in overproduction of commodity hogs, that is to say that production of commodity hogs has exceeded ability to pay for commodity hogs. Another viewpoint holds that low purchasing power is a factor causing difficulties in selling hogs, but the essence of the problem is circulation. Everyone put forward the following several suggestions.

1. Need to change the system of independent families doing business. The comrades believed that the livestock industry is funadmentally commodity production requiring full play of the role of price laws with some competition. Currently the commercial system whereby individual families do business is not compatible with commodity production, and restructuring should be done.

First, it is necessary to have collective businesses and individual businesses in addition to state-owned businesses. Second, it is necessary to permit livestock industry production units to engage in integrated production and marketing enterprises. Third, it is necessary to establish a main livestock industry company with a combining of production and marketing in the livestock industry from the central to the regional level, each jurisdiction also establishing corresponding bodies for the unified management of production and marketing in the livestock industry. Some comrades feel that this way of doing things offers five main advantages. 1. Unified leadership that helps closely coordinate production and marketing so that producers will be able to unify ownership of and rights of use of means of production, and allocation rights for products, and so that circulation will help advance development of production. 2. Reduction in the number of intermediate links, reduction of expenditures and waste, lowering of cost, and promotion of consumption. 3. Overcoming the wrangling over farm and livestock quarantines, and an early elimination of epidemics. 4. Equitable use of state funds to support production. 5. Solution to the problem of overlapping organizations for a conservation of manpower.

2. It is necessary to proceed from commodity production and break up the strict delineation of areas, permitting a mutual distribution and a mutual circulation between haves and have nots of livestock products among prefectures, among provinces, and among different systems of ownership. State planned regulation would be better, and where state regulation is difficult, automatic redistribution among prefectures, provinces, and among the people should be permitted with no delineation of territories or stifling controls.

3. Prices for livestock products should also proceed from the characteristics of commodity production of livestock products, with overall consideration given to the requirements of the laws of value. It is necessary, first of all, to readjust unfair elements in existing prices, the readjustment being both upward and downward. For example, prices for encouragement of the raising of hogs should be lowered, while prices for beef cattle and lean hogs should be appropriately raised. A lot of shouting has been done for many years about unfair parities, but now the time has come when solution has to be found. While looking on and doing nothing about the unfairness of parity prices, production is impaired, so how can we go on without finding a solution? Additionally, once readjustment has been made, prices should be gradually allowed to float. Within the upper and lower limits of floating prices uniformly set by the state, business units can allow fluctuations within prescribed limits on the basis of the relationship between supply and demand for livestock products. This would make things more and more lively and situations would be avoided in which people let meat products rot or go bad rather than lower the price, cutting off their own noses to spite their faces. This would help both production and consumption.

4. Change of the bureaucratic workstyle in business with practice of a system of responsibility in business.

5. Intensification of the building of communications and transportation. Everyone agrees that communications and transportation should be put ahead of

everything else. Many farm and livestock products or local specialties are produced in the farflung rural villages or in pastoral areas along the frontiers or in mountain regions, and because of poor transportation in some regions, products cannot be moved out. Large quantities accumulate, and this neither helps production nor consumption. Consequently, it is necessary to intensify the building of communications and transportation. If this is not done, these regions will vigorously develop livestock industry production only to be limited by communications and transportation, and the more they hurry the less their speed. Last year's discussion meeting raised this problem, and it was raised again this year. That this has been so demonstrates its importance.

IV. The Problem of Integration of Animal Husbandry, Industry, and Commerce

Countless facts show that unless China's livestock industry as well as (or even to a greater extent than) its farming industry changes its position of solely being a supplier of raw materials, and unless it breaks through the situation of serious split among agriculture, industry, and commerce, any fundamental change in prospects will be difficult. This is because price parities in the exchange of industrial and agricultural products are currently unfair. In addition, expenditures for the circulation of commodity livestock products are too great, making it too uneconomical for them to serve as consumption foods for the people. Since the Third Plenary Session of the 11th Party Central Committee, by following the guiding mentality of primary reliance on science in development of the farming and livestock industries, China's farming and livestock industries have gained a new vitality. However, the seriousness of use of economic methods to deprive peasants and herdsmen has not fundamentally changed, and this is also a fact that cannot be denied. this has been particularly true in the livestock industry. The commodity rate in livestock industry production is fairly large. In agricultural areas around 80 to 90 percent is commodities, and though personal consumption is somewhat greater in pastoral areas, the commodity rate is still very high, so the significance of the integration of animal husbandry, industry, and commerce is greater and benefits more remarkable. However, the reality today happens to be just the reverse, making experimentation very difficult and action more difficult. Almost all of the commodity livestock products are now in the hands of state-owned industries and businesses, so as soon as an integration of animal husbandry, industry, and commerce occurs, that will mean a fight for raw materials or a "shoving to get something to eat" against state owned industries and businesses. Commercial departments say this is "snatching away their rice bowls," and peasants and herdsmen say this is resisting the use of economic methods to deprive peasants and herdsmen, so just who is right? This requires a look at what methods can promote production, make the economy prosper, and serve the people's consumption endeavors. Without doubt, benefits from an integration of animal husbandry, industry, and commerce would be good.

Following several years of pilot projects and explorations, there is a renewed awareness that further pilot projects and practice in the ins and outs of this newly born matter of integrated animal husbandry, industrial, and commercial enterprises is fully necessary. Consequently, comrades attending the conference spoke glowingly of their necessity, their possibility, and the basic lessons of their experience.

(1.) China's goal in the integration of animal husbandry, industry, and commerce lies in changing the position of the livestock industry as a supplier of raw materials, to reduce the number of links in the circulation of livestock products, to conserve on circulation expenses, and to go on to eliminate various obstacles in the way of development of livestock industry production, arousing the enthusiasm for production of herdsmen, and making development of commodity livestock products commensurate with the pace of the building of the "four modernizations."

(2.) The mission of the farming and livestock industries is a steady wresting from nature of food and wealth to provide steadily increasing amounts of consumption goods for society. It is their end products that manifest their effectiveness in serving society, and their fundamental role in the national economy. These benefits and fundamental roles are the results of the common function of the three sectors of agriculture (including animal husbandry), industry, and commerce. They are mutually cooperative, mutually towing, mutually advancing, and mutually restrictive. Should this organic relationship suddenly be damaged or destroyed, the bonds of mutual cooperation being torn asunder, commodity production of livestock and farm products is bound to be impaired, or even decline and perish. The best way in which to maintain these bonds intact is to integrate animal husbandry, industry, and commerce.

(3.) For historical reasons, the situation of the price of farm and livestock products in China being at variance with their value has been very serious right up to the present day. The value of the labor used to produce farm and livestock products has not been able to be truly realized. This state of affairs has meant that numerous farm and livestock industry capital construction projects have frequently not made up the losses sustained in their construction. This was because what went into them was high priced industrial goods, but what they produced was low priced agricultural products. Development of integrated livestock, industrial, and commercial enterprises, and taking the path of the integration of animal husbandry, industry, and commerce would be that profits realized from sales and processing of commodity farm and livestock products would revert to the farming and livestock industry. This is not only right and proper, but is also workable in practice.

(4.) In operating integrated livestock, industrial, and commercial enterprises, it is essential that their superiority in quantity, quality, and economic effectiveness be shown to be incomparably greater than that of the previous industrial and commercial channels, otherwise they will lose their reason for being.

(5.) In both experimenting with and developing integration of animal husbandry, industry, and commerce, the main things must be commodity rates and quantity of commodities. In which ever way the commodity economy is more developed, it is in that way that integrated enterprises must inevitably have the greatest possibilities.

(6.) The integration of some livestock products will have to be done on a certain scale. When a unit's or a region's livestock products do not suffice for highly efficient, low expenditure economic benefits, commune and brigade, or county and prefecture lines will have to be broken through to set up integrated enterprises that are larger in scope. This may be done through production and marketing contracts, returns of profits to producers, or joint share operation.

(7.) The relationship of specialization and socialization to the integration of animal husbandry, industry, and commerce is mutually supportive and mutually advancing. Certainly the integration of animal husbandry, industry, and commerce is a result of and a product of specialization and socialization, it is, at the same time, also specialization itself. In places in which the degree of specialization and socialization is not high, operation of integrated animal husbandry, industrial, and commercial enterprises can promote increase in the degree of specialization and socialization. Once specialized contracting systems of responsibility and systems of responsibility linking output to calculation of remuneration have developed, some places will be able to make households specializing in the livestock raising industry a part of their integrated animal husbandry, industrial, and commercial enterprises.

(8.) Going in for grandiose projects and unnecessary frills is to be guarded against. The make-up of integrated enterprises has to be planned. Generally speaking, one thing should be done at a time, and when the situation is ripe for something, experiments should be run for that thing. When the situation does not permit "a coherent whole," then a "semi-coherent whole" will do (i.e. partial integration, with the integration of front parts or back parts).

Current difficulties in pilot projects for and developmnnt of integrated animal husbandry, industrial, and commercial enterprises. The opposition of some comrades in the commercial and public finance sectors is extraordinarily severe, and in most areas, public finance and commercial administrative sector sectors are not very positive about formation of "a coherent whole" in animal husbandry (farming), industry, and commerce. Some place the financial standpoint and the production standpoint in opposition to each other, believing that it is a "transfer of profits." Some are accustomed to doing business through the old channels, "using a knife to cut when there are too many, and using the lash to urge along when there are too few." They are neither good at using their own individual methods to link cities and countryside for the development of rural and pastoral sources of wealth, or seeking "ways to generate wealth," or "ways to amass wealth," and neither do they like allowing others to do any dealing. Some fear only that someone may snatch away their ricebowl, without realizing that when other people's ricebowls are carried away, there will also be those who go hungry. Therefore they "do not hesitate to kill the chicken to get its eggs," or "drain the pond to get the fish," and they are not willing, in the face of a new situation, to dynamically pioneer anew opportunities for themselves. Some of them take every opportunity to represent themselves as maintaining the welfare of the whole, and wherever the face of the welfare of the whole appears, it seems that only they represent the welfare of the whole. The so-called theory of transfer of profits," "theory of using the little to squeeze and out the big" and the "theory of using the indigenous to squeeze out the foreign" all stem from this.

In this connection, comrades attending the conference made the following suggestions about progarms and policies for integrated animal husbandry, industrial, and commercial enterprises.

First is to give to already designated pilot project units genuine rights to experiment. Second is that pilot project areas should be enlarged. All provinces should set up pilot project experiments for both pestoral areas and farming areas. Third, livestock products are second and third category commodities for which there should be no further practice of the method of "procuring however much is available." Second category products are to be part of the planned economy and should "be guaranteed without change for several years." Third category products are to be regulated by the market. Fourth, legislation should be passed pertaining to integrated animal husbandry, industrial, and commercial enterprises. Fifth, it was recommended that the State Council or appropriate departments affiliated with the Ministry of Agriculture should convene, at an appropriate time, a work conference on industry and commerce to study and formulate programs and policies, and to decide plans for pilot projects.

V. The Longrange Planning Problem

Delegates further explorted the importance and position of the livestock industry and formulated a foundation, goals, and basic content of longrange plans. They also stipulated that plans must proceed from the situation existing in China and be in accordance with existing capabilities. On the basis of the seeking of truth in facts and concern for economic results, emphasis was given discussion of several tactical problems of development in longrange plans for the livestock industry. These were as follows:

1. Strategy for Technical Development

Just what strategy should be practiced in the technical development of China's animal husbandry? Would it be proper to adopt traditional development strategies using the United States and the Japan of today as the developmental goals that technical development of China's livestock industry should imitate, taking the road of high investment of capital, high structuring, high possession, high energy consumption, and high output value. Would this result in high benefits? What development strategy should be adopted in view of China's national situation? Currently there are three views.

One, based on a survey of large Beijing chicken farms, holds that Beijing's several chicken farms are large in size, have great output, and profits approaching 1 million yuan; therefore, henceforth, there should be continued development of large scale mechanized and factorized raising of chickens and hogs.

A second holds that the indigenous and the foreign should be practiced at the same time, that the large, the medium, and the small should be developed simultaneously, and that a program of mechanization, semi-mechanization, and hand operation should be employed at the same time.

The third view holds that in its use of superior varieties, importation of Peruvian fish meal and Japanese ammonium nitrate to produce full value livestock feeds, and in its invitations to experts and professors in institutions of higher learning to give technical guidance, Beijing possesses material and technical advantages such as other provinces and municipalities in the country are unable to match. Therefore, the several large chicken farms in Beijing showed profits while most of the country's mechanized and semi-mechanized chicken farms were in dire straits. The livestock industry is part of the commodity economy in which use of any technical measures requires adherence to the principle of final products, and the kind of economic results as standards for judgment. These also establish estimatively the critical points and the optimums for technological investment. Therefore, advantage should now be taken of a plentiful workforce and the low value of labor to put efforts into biological technology requiring relatively small investment (superior varieties, building of grassy plains, grassy mountains, and grassy slopes, and the processing and production of balanced cattle feeds).

2. Strategy for Economic Development

The long enduring practice of the past whereby an economy owned by all the people was the only legal economic form, the collective economy was a traditional economic form, and the individual economy was a remnant of capitalism, with the adoption of measures restricting or prohibiting commune members in the raising of poultry and livestock was wrong. Henceforth, a livestock industry economy that is diversified in form should be developed; however, three different academic points of view exist as to how it should be developed.

One advocates a "primary and secondary theory," and opposes combinatorial theory, believing that public raising and private raising should be practiced simultaneously in a program whereby public raising is primary in order to strengthen the collective economy. In a socialist country such as ours with its system of ownership founded on production teams in people's communes, this method is more suited to levels of production, and there is need to guard against vacillation on both [the public and private] sides.

The second advocates systems theory and combinatorial theory, but disagrees with reticulation theory [4854 4158 6158], primary and secondary theory, substitution theory, and arbitrary uniformity. The primary and secondary theory viewpoint does not square with objective realities, Except for the numbers of cattle now being raised in pastoral areas, in terms of the country as a whole, the overwhelming source of livestock products is individual livestock raising, and the portion raised publicly has never held a "primary" position. Inference on the basis of the "primary and secondary theory" can lead to the conclusion that large amounts of manpower and financial resources should now be used to develop the public cattle raising portion until it accounts for more than half of all cattle raising. Deduction from "primary and secondary theory" places in mutual contradictory positions CCP Central Committee Document 13's decisions on "All Matters Suitable for Individual Commune Member Operation Should Be Done to the Maximum Extent Possible by Peasant Households," and the thesis of the Central Committee that China's is a socialist commodity economy with a diversified ownership structure in which public ownership predominates. Application of the viewpoint of systems theory means that the livestock industry is a system of economic control composed of the breeding system, the livestock feeding system, the quarantine system, and the procurement, storage and transportation system, and is not limited to some direct cattle raising units. Proceeding from China's current levels of productivity, even though fairly good economic results have admittedly derived from the individual and collective livestock raising industries, the economy of ownership by all the people has greater advantages in breeding, livestock feeding, quarantine, procurement, and storage and transportation. In these fields the state-owned economy should actively develop, and this development should provide active support to the individual and collective livestock feeding industries. On the basis of help to them in achieving increased output and increased earnings, all of most livestock products should be made a part of planned markets. Therefore, it is necessary to devise overall strategies for the animal husbandry economy as a whole. Assessment should not be made solely on the basis of quantity of livestock raising being done to determine who is primary and who is secondary, but rather on the principle of cooperative specialization. On the basis of the strengths and weaknesses of various economic systems and requirements in development of the objective system, making the most of advantages and downplaying of disadvantages, and an equitable division of labor should be done to bring their production potential fully into play and create greater social material wealth to achieve a balance between the haves and the have nots, each being properly provided for. In this way both the structure and the organization are made equitable, and the superior position of the system of public ownership continues to be maintained. All that is required for state and collectively owned livestock farms is a restructuring of their methods of operation to derive better macroeconomic results, and they too will be able to attain the development they should have. At the present time when there is a seller's market for most livestock products, no problems at all exist in a possible overwhelming of the state-owned and collective economy by the commune member livestock raising industry. Proceeding from this viewpoint, there should be gradual change in the different policies towards the state-owned the collective, and the individual economy in procurement prices paid and award sales standards for livestock products, all being treated equally without discrimination.

3. Strategies for Livestock Fodder Development and Use

China's strategy for development of livestock fodder should be as follows: To make full use of the abundant workforce, and use every possible means to use resources that have not yet been used to hasten the building of grasslands in pastoral areas, to develop grass covered mountains and slopes in farming areas, and to go in big for comprehensive use of agricultural sideline products to solve the problem of insufficient grass and fodder for livestock.

4. Establishment of an Integrated Economic Management System With Entrepreneural Administration That Is Both Able to Enliven the Micro-economy and Able to Strengthen Macro-planning and Management

Analysis using cybernetic theory shows the existing system of management to be an administratively centralized cybernetic system that uses administrative methods to control the economy. Within the system, departments stand independent of each other, one area is separated from another, suppliers, producers, and marketers have no face to face dealings with each other, manpower, finances, and materials are individually managed, and individual components frequently shift their problems to others. Territories are strictly staked out, and there is frequently ceaseless wrangling and interminable conflicts. In performance of work there is neither dynamism or restraint. The system can neither vigorously support peasants and herdsmen in development of production to enliven the micro-economy, nor is it able to vigorously strengthen planning and management in the macro-economy. As the economy of the livestock economy develops and diversified economic forms appear, the unsuitability of this system becomes more and more apparent. Everyone believes that longrange plans should include the issue of system reform.

Some delegates put forward the idea of an integrated economic management system that is graduated, has numerous steps, and is entreprenurially administered. They proposed a gradual change in livestock administrative organizations below the provincial and municipal levels to an entreprenural livestock company uniformly organizing within the company on the systems theory concept all breeding, livestock feed, veterinary medicine, procurement, storage and hauling, sales, funds, and materials units using the principles of contract administration and specialized cooperation for the integration of supply, production, and marketing, and of manpower, finances, and materials. Within the company, a system of hirings would supplant the appointment system, and fluctuating wages would replace fixed wages. An election system would take the place of the life tenure system; a system of responsibility would replace the eating out of a large common pot, and sole financial responsibiligy would take the place of uniform receipts and uniform expenditures.

5. Systematic and Scientific Development Strategy for Information, Consultation and Decision Making

Levels of development of China's livestock industry economy are fairly low and mistakes have been many. Though much has been invested, there has been considerable waste. One of the reasons has been no establishment of a scientific news, consultation, and decision-making system, which has resulted in mistakes on numerous occassions, and payment of substantial "study expenses."

(1) Establishment of a self-contained, accurate, information system. (2) Establishment of a consultation system that includes technology and economics. (3) Establishment of a system of responsibility for decision making. Leaders must make prudent decisions about major projects on the basis of collective study; decision makers must bear economic consequences for their decisions (bearing legal consequences for major mistakes); and they should enjoy economic benefits from correct decision-making.

6. Strengthening of Livestock Economy Research, and Doing a Good Job of Building Science and of Education.

Research on the livestock economy is gradually becoming more penetrating. Academically, discussions at this conference on five special topics were on a higher plane than last year, and numerous new situations and new problems requiring study were put forward. Additionally, numerous new sciences have begun to be introduced into studies, sciences such as macro-economics, micro-economics, eco-economics, systems engineering, and futurology.

Nevertheless, livestock economy studies have also shown themselves to be out of touch with requirements of situations, and henceforth the task should be to further systematize and make more scientific studies of the livestock industry economy, establishing as soon as possible a self-contained and independent branch of learning for livestock industry economics.

ANHUI STATE FARMS IMPROVE ADMINISTRATION, READJUST ECONOMIC STRUCTURE

Beijing ZHONGGUO NONGMIN BAO in Chinese 11 Feb 82 p 1

[Article by Wang Peiyi [3076 1014 3015]: "Anhui State Farm and Land Reclamation System Turned Losses into Profits in 1981 Through Improvement in Administration and Management and Readjustment of Economic Structure"]

[Text] The Anhui state farm and land reclamation system, which has showed losses for the past more than 30 years, improved its administration and management in 1981 and readjusted its economic structure to make a profit of 5 million yuan.

In 1979, this province's state farm and land reclamation system converted losses into profits for the first time; however, as a result of serious flood disasters the following year, it again ran losses of more than 13 million yuan. In 1981, leaders of the provincial state farm and land reclamation system assiduously summarized the lessons of historical experience and took firmly in hand a restructuring of administration and management and economic readjustment work centered around a system of responsibility for production. The 348 agricultural production teams throughout the system set up systems of responsibility, whose main ingredients were "contracting, fixed outputs, and awards," which strengthened the sense of being masters in their own house among the farms' employees, and readjusted the economic structure within the state farm and land reclamation system. They also put to full use the abundant natural resources of barren mountains, wastelands along bodies of water, lakes, reservoirs, ditches, and ponds in vigorous development of economic diversification. Now their diversification involves 94 different items, which have increased their earnings and laid a foundation for development of integrated agricultural, industrial, and commerical enterprises.

The Anhui state farm and land reclamation system plans next year to set up nine more integrated enterprises on the foundation of eight existing agricultural, industrial, and commercial integrated enterprises; and, prior to 1983, it intends that the state-owned farms throughout the province will little by little become a part of or operate integrated enterprises, expand integration with rural communes and brigades, and build state farms with all possible speed into burgeoining enterprises with all-around development of farming, forestry, livestock raising, sideline occupations, and fisheries that carry on integrated agricultural, industrial, and commercial activities.

BRIEFS

LISTS OF ACHIEVEMENTS--1. The province had an overall bumper harvest. The income and savings deposits of commune members broke through the highest historical levels. 2. In Huadong Prefecture, connecting tracks were laid on the important Anhui-Jiangxi railroad trunk line. 3. Big achievements were made in the construction of the Two Huai (Huainan and Huaibei) coal base. The Liuqiao coal mine, with a designed annual production capacity of 600,000 tons of coal, was completed and put into operation; the Luling coal mine, with the capacity to dress 1.8 tons of raw coal a year was completed and put into trial operation; and in the Zhunbei powerplant of the Kengkou power station, a 200,000-kilowatt generator was integrated with the power network and is producing electricity. 4. In 1981, the volume of direct export commodities reached $86 million, an increase of 1.15 times over that of the previous year and an increase of 3.5 times over than of 1979. 5. The China Sciences and Technology University basically completed the predevelopment and manufacture of the physical design and key parts for the Hefei synchronous radiation unit. BEIJING

REPORTER CALLS ATTENTION TO SUGARBEET WASTE IN HEILONGJIANG

Beijing GUANGMING RIBAO in Chinese 5 Feb 82 p 2

[Letter from staff reporter Zheng Xiaofeng [6774 4562 2800]: "The Alarming Waste of Sugarbeet Resources Should Be Stopped Immediately"]

[Text] Editorial Department:

Recently I went to the main sugarbeet-producing region of Heilongjiang Province to cover a story and saw that, in a year of great natural disasters, a bumper harvest had been reaped from the large area planted with sugarbeets and that the total output had reached the level of the high yield of the year before last.

The party's policies had promoted a high yield in agriculture, but some of our departments had artificially caused a great amount of waste in what had been harvested and was on hand. The purchasing station in Anda County, based on its self-determined "purchasing standard," compelled the peasants who were selling sugarbeets to pare off, as impurities, the green tops and outer skin of the sugarbeet nodes, and these contain a lot of sugar. By making this demand in purchasing sugarbeets, viz, paring the sugarbeet node, which weighs 1 or 2 jin, until the white flesh of the beet is exposed, at least 5 qian [1 qian = 5 grams] of a sugarbeet node is cut off. Calculating on this basis, last year Heilongjiang Province pared away one sugar refinery's output. The masses there reacted extremely strongly to this. They said, "This kind of action, which wastes and harms the state's wealth, is simply a crime."

Specialists of the Sugarbeet Research Institute of the Chinese Academy of Sciences, with extreme bitterness, did an accounting: taking the base number of 3,500 sugarbeet seedlings per mu, and an average of 5 gian being pared off each sugarbeet, 175 jin of sugarbeets were pared off 1 mu. Last year Anda County planted sugarbeets on 230,000 mu. With the paring off of 20,125 tons of a high yield of sugarbeets already in hand, calculating 85 yuan in profit per ton of sugarbeets, the county lost 1,710,625 yuan. Calculating the sugar content at 15 percent, this one county of Anda, pared away for nothing 6,037.5 tons of white sugar. Ping Yulin [7458 3768 7792], deputy director of the Sugarbeet Research Institute, said: This method of paring sugarbeets, which alarmingly damages the state's source of refined sugar, is not confined to this one county of Anda. Both Hulan and Lindian Counties had purchased according to this purchasing standard. Last year Heilongjiang Province's acreage under sugarbeets was 3,842,000 mu. Substracting the acreage which had a reduction in output owing to natural calamities, and thus calculating on the basis of 3.2 million mu, the province will lose 280,000 tons of sugarbeets, equivalent to losing for nothing 84,000 tons of white sugar. Calculating on the basis of 1,600 yuan in income per ton of white sugar, this will cause the huge loss to the state of over 130 million yuan. This is an alarmingly big waste at one stroke.

Why is it that up to now it has been impossible to stop such a huge waste in the sugarbeet purchasing process? The reason is that in some sugar refineries in the province, production techniques are backward and sugar output is low. They do not pay attention to improving the backward production techniques, but instead set their own policy of raising the purchasing standard, without regard for the great amount of waste caused to the state's resources, in a one-sided pursuit of their own sugar output rate. What is strange is: this act of seriously wasting society's wealth, which cheats the state, the collective and the peasant, receives the tacit consent of the leading departments concerned.

The specialists suggested to this reporter that he publish in a newspaper this "economic accounting," which represents a great amount of waste of the state's resources, in order to draw the attention of various quarters to the need quickly to plug this damaging and wasteful leak.

AGRICULTURAL DEPARTMENT OFFICIAL VIEWS SPRING PLOWING SITUATION

Lanzhou GANSU RIBAO in Chinese 12 Feb 82 p 1

[Interview with Comrade of Provincial Agriculture Department by staff reporter: "Strive for Greater Agricultural Development This Year Than Last"; date and place not specified]

[Text] Recently, this reporter interviewed a responsible comrade of the provincial agricultural department with regard to the question of spring plowing and production. He said: This year we must, using all ways and means and by getting started as early as possible, strive for a greater development in agriculture than there was last year.

Question: What is the general situation in spring plowing and production in our province this year?

Answer: The situation in spring plowing and production in our province this year is fairly good. Following the further implementation of the party's policies and principles and the gradual perfection of various forms of the production responsibility system, the production enthusiasm of the broad masses of peasants is becoming greater and greater. In addition, the weather has been comparatively good. Throughout the province, 1 million mu more of overwintering crops have been planted than last year; 600,000 mu more of land was irrigated in the autumn and winter than last year; and there is close to double the amount of water stored in reservoirs than last year. In production preparations--the land plowed in the hot months and autumn and the accumulation and shipment of fertilizers and seeds--a more solid job was done than in previous years, and at present in most places the soil moisture content is better than in previous years. These are all favorable conditions for doing a good job in spring plowing and production this year. At the same time, it must be seen that some places in the central region received little rain and snow last autumn and winter so that the soil moisture content is deficient, and the supply of drinking water for people and livestock is relatively difficult. In some places in the winter wheat producing areas, because after sowing the cumulative temperature was low and the base fertilizer was insufficient, the wheat seedlings grew weakly and their tillering was deficient. All these things have an unfavorable effect on spring plowing and production in some places.

Question: In order to do a good job in this year's spring plowing and production, what questions need to be addressed?

Answer: First of all, a good job must be done in winter wheat field management. In our province, winter wheat occupies close to half the acreage as that of summer grain crops, and tightly grasping the opportune moments to do a good job in the field management of winter wheat has a great bearing on the wresting of a bumper harvest of summer grain crops this year. If there is a bumper harvest of summer grain crops, we will gain the initiative for the whole year. Every locality must organize cadres, agrotechnicians and experienced peasants to go into the field and make a general survey of the wheatfields, analyze the condition of the young plants, focus on existing problems and take appropriate management measures. At present, in the winter wheat areas the soil moisture content is generally good and the stocks of chemical fertilizers are relatively ample. Each place must tightly grasp the opportune moments before and after the thaw to apply a topdressing of chemical fertilizer so as to promote an increased production of strong sprouts. According to surveys this year, it is very possible that the wheat stem rust in southern Gansu and the (?red dwarfism) [hongaibing 4767 4253 4016] in eastern Gansu will spread to other parts of the province. Every locality must conscientiously strengthen their forecasts of plant diseases and insect pests, make good early preparations of preventive agricultural chemical equipment and do preventive work before plant diseases and insect pests appear in large numbers.

Second, under the guidance of the state plan, carry out the various planting plans in line with local conditions. The agriculture economy must give priority to planning, with market regulation made supplementary. The development of agricultural production must be carried out according to the state plan. We must educate the broad masses of peasants to consider the overall situation and the collective and, in line with the state's requirements, take into account the interests of the state, the collective and the individual and, under the guidance of the state plan, carry out planned planting. We must actively pursue economic contracts, linking the production activities of the collective and the individual commune members to the state's planned arrangements and truly complementing the state's plan. When plowing is begun throughout the province, we must, proceeding from Gansu's actual conditions, actively carry out the policy of "without slacking off on grain production, actively develop a diversified economy"; readjust the distribution of crops in line with local conditions and, while getting a tight grip on grain, actively develop economic crops like oil-bearing crops, beets, cotton, flue-aired tobacco and vegetables; and make full use of this year's advantageous conditions of plentiful irrigated land and good soil moisture content to insure that, according to plan, the planting is done well and in sufficient quantity.

Third, energetically popularize agricultural science and technology so that the land is tilled scientifically. Every locality must list the popularizing of agricultural science and technology as an important item on its daily agenda and conscientiously strengthen leadership over the work of agricultural science and technology. They must, in a planned way, organize scientific and technical personnel to get deeply involved with production and the masses, to study and solve the actual problems in agricultural production that urgently need to be solved and to resolutely change the situation in which scientific research and production are disjointed. The main effort of scientific and technical departments must be placed on doing research in applied science and on popularizing advanced techniques, so as to serve current agricultural production. They must sum up the practical experiences of the masses gathered over many years and develop the traditional farming techniques of intensive cultivation. They must vigorously recommend and popularize advanced scientific techniques that the masses will be glad to accept, that produce quick results and that bring in more income. This year, on the basis of popularizing well the 19 scientific and technical items already decided upon, they must focus on doing a good job of demonstrating and popularizing major scientific and technical achievements, which have a wide range and produce quick results, such as the widespread production of the seeds of Zhongdan No 2 corn and in 2148 wheat, the spraying of leaves with phosphoric acid phosphate 2 hydropotassium and the nonpotato virus strain of potato. They must vigorously promote the contract system for popularizing agricultural science and technology, organically combining scientific research and popularization work and insuring the popularization and application of every item of agricultural advanced science and technology.

Four, get started as early as possible on efforts to do a good job in taking precautions against or resisting natural calamities. At present, in most places in the counties of Huining, Jingyuan, Gaolan and Jingtai, the water content of the tilled layers of soil is generally less than 10 percent. Leaders at all levels in these places must pay a high degree of attention to this situation and immediately mobilize and organize the broad masses to conscientiously do a good job of taking precautions against drought during spring sowing. They must conscientiously check the soil moisture content, sowing summer grain wherever it can be sown and if the moisture content is deficient, they must not plant summer grain. They must make early preparation of autumn grain seeds, so that autumn grain will supplement summer grain. Concerned departments at the province, prefecture and county level must continue to help these places to solve the problem of providing drinking water for people and livestock. The other places must also always be on the alert and be prepared at any time to struggle against natural calamities that might occur, so that their preparedness will avert peril and they will have seized the initiative.

Five, conscientiously change the work style and earnestly strengthen concrete leadership over spring plowing and production. A large group of cadres must be organized, led by a responsible comrade, to go to the frontline of spring plowing and production to conduct protracted, constant propaganda among the broad masses of basic-level cadres and peasants with regard to upholding public ownership of land and other means of production and to practicing the production responsibility system in the collective economy. No matter what form of the production responsibility system is adopted, if the masses do not want changes then do not make changes, so that the masses will be easy in their minds and do a good job in every part of the production. A tight grip must be kept on the signing of all kinds of contracts, work exchange and mutual help of a mass nature must be developed extensively and households with difficulties must be helped to do a good job of spring plowing and sowing. During the busiest period in spring plowing, the county and commune cadres, particularly the leading cadres, must stick to their work posts, take part in production, correctly direct production and firmly overcome some bad tendencies at the basic level such as slack and weak work, nobody being responsible for a piece of work and being absent at will from one's work post without permission. All trades and professions must vigorously support spring plowing and production, insuring in all aspects the completion of the tasks of spring plowing and production.

EFFORTS TO INCREASE QUANTITIES, KINDS OF CHEMICAL FERTILIZERS REPORTED

Proper Kinds, Use of Chemical Fertilizer

Guangzhou NANFANG RIBAO in Chinese 12 Feb 82 p 2

[Article by Lin Guoxiong [2651 0948 7160], Special Correspondent]

[Text] In speaking about problems in the extension of agricultural research and techniques in the government work report he made to the Fourth Session of the Fifth National People's Congress, Premier Zhao Ziyang hoped that a change in chemical fertilizer composition and sensible fertilization could produce more outstanding accomplishments within a relatively short period of time. This hope also has great pertinence for Guangdong Province, and should be diligently studies for a solution.

At the present time, two conspicuous problems exist in Guangdong Province's chemical fertilizer production, supply, and utilization.

First is an inequitable composition of chemical fertilizer in which the proportions of nitrogen, phosphate and potash are not in balance. There are 60 large and small nitrogenous fertilizer plants in the province with an annual production capacity of 2.9 million tons, and 37 phosphate fertilizer plants with an annual production capacity of 1.1 million tons (though actual output does not reach designed capacity), but there is not a single potash fertilizer plant, nor is there a plant that produces compound nitrogen, phosphate, and potash fertilizer. Most of the fertilizer dispense by the central government and that imported by the province is nitrogenous fertilizer, and this further accentuates the proportional imbalance among nitrogen, phosphate, and potash. In 1980, for example, quantity of chemical fertilizer used in the province was 3.82 million tons, of which the ratio of nitrogen, phosphate, and potash was 1:0.23:0.088. Not much change has taken place in these ratios during the last 2 years. Clearly this cannot meet the physiological growth requirements of farm crops inasmuch as the ratio of requirements for nitrogen, phosphate and potash for most farm crops is 1:0.5:1.

Second is the serious waste and loss through runoff of chemical fertilizer, making for a not very high utilization rate. Measurements made by agricultrual science units show the utilization rate of chemical nitrogenous fertilizer (absorption by crops) to be only between 35 and 50 percent, of phosphate fertilizer 10 to 25 percent, and of potash 30 to 60 percent. Research data show that in foreign countries generally 1 jin of chemical fertilizer can increase grain output by 5 jin, while in Guangdong Province the average increase is only slightly more than 2 jin. The main reasons for the low chemical fertilizer utilization rate are: first, poor packaging, storage and transportation, which causes nitrogenous fertilizer to volatilize. Second is faulty methods of putting down fertilizer causing surface runoff. Thid is ground percolation. In gravelly, porous fields, in particular, loss is greatest. Fourth is dissipation into the air of free state nitrogen (N_2). Temperatures are high in Guangdong Province, and when ammonium-state nitrogen is spread on the soil surface, particularly on alkaline soil, it will gradually liberate ammonia, which volatilizes.

This demonstrates that the utilization potential for chemical fertilizer is very great. Currently Guangdong Province annually uses more than 3 million tons of chemical fertilizer. Were the utilization rate for chemical fertilizer to be raised by 20 or 30 percent, that would equal between 600,000 and 900,000 tons of chemical fertilizer, producing an increase in grain output of between 2.4 billion and 3.6 billion jin, figuring a grain output of 2 jin per jin of chemical fertilizer, and making for extremely impressive economic benefits. Therefore, it is suggested that the following actions be taken:

(1) Gradual restructuring of the composition of chemical fertilizer to increase the phosphate and potash content. In order to change the imbalanced ratio of nitrogen, phosphate, and potash, in addition to running existing nitrogenous fertilizer plants well to upgrade quality and increase quantity, packaging, storage, and transportation should be improved to reduce losses insofar as possible. Existing phsophate fertilizer plants in the province should think of every way possible to increase output of phosphate fertilizer. Because of a lack of sea transportation capacity the Zhanjiang Phosphate Fertilizer Plant, the plant in the province with maximum phosphate fertilizer output, amounting to 250,000 tons annually, loses several tens of thousand tons to other provinces. It is recommended that the province's shipping sector increase the number of ships transporting phosphate fertilizer, and institute transportation on certain ships over certain routes to prevent further phosphate fertilizer from slipping away to other provinces. In future imports of chemical fertilizer, quantities of phosphate and potash should be increased.

(2) It is recommended that chemical fertilizer and organic fertilizer be used in combination. Organic fertilizers such as much fertilizer, barnyard manure, and green manure are sticky in nature. By using them in combination with chemical fertilizer, they will wash away less readily and the supply of nutrients will be evely balanced, and not only will increased yields derive from the immediate crop, but soil will be improved as well. When the phosphate and potash mixed in with organic fertilizer is fully composted for use as a base fertilizer, the effectiveness of the fertilizer is greatly increased.

(3) Scientific use of fertilizer. First of all, nitrogenous phosphate and potash fertilizers should be properly mixed and a change made in overfertilization with nitrogenous fertilizer, which leads to spindling of stems and leaves, disease and insect pest infestations, and lodging. Secondly, in light of the numerous paddy fields and large quantity of rainfall in Gunagdong Province, the scatter method of applying fertilizer must be resolutely reformed, and the deep layer application method promoted in order to reduce the volatilization and runoff of chemical fertilizer.

(4) Strengthening of technical guidance so that fertilization will be done in the right amounts at the right time. Now that the rural villages of the province have universally instituted various forms of a system of responsibility for production, the peasants urgently require a strengthening of guidance in agricultural techniques. We must adapt to these circumstances and vigorously promote methods for the scientific use of fertilizer, increase the utilization rate of fertilizer, and obtain benefits in greater output and greater earnings.

Readjusted Small Plants

Guangzhou NANFANG RIBAO in Chinese 9 Feb 82 p 1

[Text] Readjustment of Guangdong Province's small nitrogenous fertilizer industry, diligent reorganization of enterprises, and restructuring of technology has brought fine economic benefits. Not only has there been no decline in nitrogenous fertilizer production by small plants, but expenditures have also dropped, the number of profitable plants has increased, and the number of non-profitable plants decreased.

Guangdong's small nitrogenous fertilizer industry got its start in 1961 and had 86 plants by 1981, providing a total of 5.47 million tons of nitrogenous fertilizer for agriculture. On the basis of output in 1978, small nitrogenous fertilizer plants provided Guangdong Province's agriculture with 23.8 kilograms of nitrogenous fertilizer per mu of cultivated land. Thus it provided agriculture 80.6 percent of the total amoung of nitrogenous fertilizer produced in the province, fully demonstrating the important role of small nitrogenous fertilizer plants in supporting agriculture. However, in the building of a small nitrogenous fertilizer industry, some problems also existed. There were too many individual plants; the scale was too large; facilities were insufficiently balanced or insufficiently equipped, and economic benefits were rather poor.

In view of the above situation, those in charge of the chemical fertilizer industry in Guangdong Province began in 1979 to act on the principle of "reorganization and upgrading, selective restructuring, and gradual readjustment with no further new sites," to carry out a reorganization and restructuring of various kinds in the province's small nitrogenous fertilizer plants. In the case of small nitrogenous fertilizer plants not having the objective conditions needed to produce, and those for which it would be difficult to change a loss situation, closing, merging, suspending and retooling was done. Between 1979 and 1981, readjustment resulting in the closing and suspension of 37 small nitrogenous fertilizer plants was done, thereby enabling a concentration of funds and energy so that other small nitrogenous fertilizer plants possessing fairly good objective conditions could operate well. For those small nitrogenous fertilizer plants retained, emphasis was placed on conservation of energy, reduction of expenditures, and converting losses into profits in a diligent reorganization, improvement of administration and management, and increase in economic benefits. At the same time, some small nitrogenous fertilizer plants possessing fairly good objective conditions and having fairly high economic benefits were selected for technical upgrading and appropriate expansion of the scale of production, turning them into maninstay small nitrogenous fertilizer plants. After 3 years of efforts, the province now has 19 small nitrogenous fertilizer plants with an annual capacity to produce syntehtic ammonia that has grown from between 3,000 and 5,000 tons to between 5,000 and more than 10,000 tons. Though readjustment during the past 3 years has resulted in the closing or suspension of some plants, the province's output from small nitrogenous fertilizer plants is still higher than 1978 production levels. In addition, quality of nitrogenous fertilizer has improved, and energy consumption has dropped. Statistics show that in 1978, only 68 percent of the ammonium carbonate used for the small nitrogenous fertilizer industry was first quality while in 1981 the percentage had risen to 81. Coal consumption per ton of synthetic ammonia produced for the small nitrogenous fertilizer industry was somewhat more than 3,300 kilograms in 1978. In 1981, consumption declined to somewhat more than 2,500 kilograms. Electricity consumption per ton of ammonia was slightly more than 1,700 kilowatt hours in 1978, but in 1981 it fell to slightly more than 1,500 kilowatt hours. As a result of the decline in consumption for the three years 1979 to 1981 alone, the industry saved the country 316,000 tons of coal, and 80 million kilowatt hours of electricity. Furthermore, as a result of the past 3 years of reorganization and restructuring, the number of profitable plants in the industry has increased and the number of unprofitable plants decreased. The small nitrogenous fertilizer plants in Foshan Prefecture and Meixian Prefecture have turned all their losses into profits.

Increased Use of Potash

Guangzhou NANFANG RIBAO in Chinese 4 Feb 82 p 2

[Text] Guangdong Province's agricultural production has made new progress in promotion of potash fertilizer for use. In 1981, 15 million mu of the province's cropland used potash fertilizer. This was a 5 million mu increase over 1980, and generally increased yields were produced. Surveys done in Meixian, Kaiping, Huiyang, Zengcheng, and Dongguan counties showed that when potash fertilizer was applied to potash deficient soil, paddy rice yields increased by from 10 to 30 percent, and varying degrees of increase in yields also occurred for sugarcane, peanuts, sweet potatoes, and jute.

Potash fertilizer is one of the "three main elements" in fertilizer that is indispensable to crop growth. Guangdong Province has high temperatures and much rainfall, and weathering and leaching are strong. This plus the universal promotion of the growing of high yield varieties, of steady increases in the multiple cropping index and levels of output has meant an ever increasing depletion of potash in the soil. However, for a long time fertilization with nitrogenous and phosphate fertilizer has steadily increased in the province, while fertilization with phosphate has been extremely limited. This has produced an increasingly serious lack of phosphate in the soil, which has impaired increased crop yields. In light of this situation, in recent years every prefecture in the province has linked soil surveys to diligent experiments in the use of potash fertilizer, and they have also done demonstrations and conducted propaganda promotion. In 1981, quite a few places made use of potash fertilizer a major action for increasing agricultural yields. In 1981 Huiyang County put together 1,080 tons of phosphate fertilizer for use on an area of 130,000 mu for an average of between 15 and 30 jin of potash per mu, which produced very clear increases in yields. In 1981, Chenjiang Commune in this county used potash on an area of more than 3,200 mu or 70 percent of its paddyfield area. Despite serious disasters, paddy yields averaged increases of slightly more than 60 jin per mu over 1980. At Jinji Commune in Luoding County, the soil was seriously deficient in potash causing widespread outbreaks of leafspot of rice. For the 1981 late crop, the commune summarized the experiences of individual peasant households in gaining increased yields from the early crop through increased fertilization with potash fertilizer. The entire commune promoted fertilization with potash over wide areas, covering an area of 10,000 mu. As a result, incidence of leafspot was greatly reduced in a year of great disasters, the commune's late crop brought in a 200,000 jin increase in paddy over 1980.

OVER 80,000 FARM MECHANICS GIVEN TRAINING

Guangzhou NANFANG RIBAO in Chinese 5 Feb 82 p 1

[Article: "More than 80,000 Farm Mechanics Trained In Province in 1981"]

[Text] Last year farm machine units and farm machine schools at all levels in the province used diverse methods to train more than 80,300 mechanics for farm machines of different kinds, making a contribution in promoting development of farm machine endeavors.

In the wake of establishment of various forms of rural system of responsibility for production, the number of tractors used in farming by collections of individual peasant households has steadily increased, and numerous peasants urgently need to increase their knowledge of farm machine mechanics. In order to meet this new situation, farm machine units and farm machine schools at all levels used a combination of surrogate teaching, group teaching, and schools and communes (and plants), as well as teachers sent out to train mechanics for communes and brigades. Inasmuch as Shunde County has many economic crops, and many motorized boats, and since commune and brigade enterprises there have developed fairly rapidly, the Shunde County Farm Machine School also trained commune and brigade electricians, diesel power generator unit managers, farm electricity managers, boiler operators, turbine operators, motorized boat drivers and mechanics. As a result of the steady increase in motor vehicles used in agriculture, the farm machine schools in some counties also took responsibility for training drivers for farm vehicles.

Guangdong Province's farm machine training network has now been substantially completed. The province, prefectures, and counties have farm machine schools, and most communes also have certain training capabilities.

BRIEFS

GUANGDONG AFFORESTATION EFFORTS--Last year the Tongshi reclamation area in Guangdong Province planted 22,500 mu of shelter forests and economic forests and grew more than 12 million saplings. As of the present time, the reclamation area has afforested a total of 252 million mu. Last year, the Tongshi reclamation area instituted a general system of responsibility in forestry whereby it contracted plantings, survival, and care to increase the survival rate of trees that had been planted. Early last year, Longjiang Farm planned the land to be afforested and set up a special afforestation corps, with individuals being assigned duties. Once a tract had been planted, an individual was designated responsible for taking care of it to ensure survival of afforested areas. Last year, the farm planted more than 2,300 mu of shelter forests with a survival rate of 95 percent. All farms also layed out an equitable distribution of trees, planting in the designated areas Casuarina equiselifolia, Eucalyptus parvifolia, Eucalyptus rubusta, and Taiwan Acacia confusa as shelter forests, while at the same time vigorously afforesting economic forests as well. The state-owned Xinjin Farm treated afforestation as an important task, devoting great attention to it, and preserving each mu planted. Over the years, Nanmao Farm has afforested 1,000 mu of economic forests. The Eucalyptus citriodora that have been planted can be used not only for roof purlins, but each tree can annually provide about 2 jin of Eucalyptus citriodora oil, providing an income of more than 930 yuan per mu. BRIEFS

RECORD LAMB PRODUCTION--Since the 3rd Plenum of the CCP Central Committee, lamb production in Hebei Province has expanded by a fairly large amount every year for 2 consecutive years. In 1980, the numbers of lamb in inventory in the province were 8.1486 million head, the numbers removed from inventory were 1.7486 million; both figures were the highest in provincial history. In 1981, the numbers remaining in and removed from the provincial inventory further expanded; they reached 8.4233 million head and 2.4353 million head respectively, an increase of 3.4 percent and 39.3 percent over 1980. [Excerpt] [Shijiazhuang HEBEI RIBAO in Chinese 19 Mar 82 p 2]

FAT HOG INVENTORY REMOVAL RATE--In recent years, the rate of fat hogs being removed from inventory in Hebei Province has continuously increased, as have the numbers of head removed from inventory. According to statistics, the fat hog removal rate from inventory in 1979 in Hebei was 54.3 percent and the numbers of fat hogs removed from the inventory were 6.767 million, the highest level in the province's history. In 1980, fat hog removal rate from inventory was 52.4 percent and the numbers removed were 7.089 million head; although the rate of removal decreased somewhat, the numbers of head removed increased by 4.6 percent, still a historical record for the province. In 1981, the rate of removal reached 57.6 percent, a large increased over 1980; numbers of head removed reached 7.454 million, an increase of 364,000 head over 1980, reaching the highest levels in the province's history for 3 consecutive years. HEILONGJIANG

BRIEFS

OIL-BEARING CROP PROCESSING--Last year the grain departments throughout the province processed 170 million jin of small oil-bearing crops, setting for our province a new record in this respect. Both the amount processed and the amount of oil produced were raised by 1.6 times as compared with those of 1980. In order to expand the capacity of oil-bearing crop processing, the provincial grain bureau renovated some older factories and allocated 110 pieces of special-purpose equipment, which were installed and put into operation that year and which produced results that could be seen in the same year. For the whole year, the income from processing equaled over 2 times the total investment. The grain administration bureaus in Nenjiang and Huankua, the key oil-bearing crop-producing areas, also formed technical teams that went from factory to factory providing technical guidance and timely solving key production problems, so that the amount of crops being processed continually increased and the oil-extraction rate continually rose. The average oil-extraction rate for the whole year rose 1.71 percent over the state's prescribed standard, and the oil produced for the year increased by 414 million jin, with a value of over 9 million yuan. Oil-bearing crop processing factories throughout the province have widely popularized the method of using sunflower seed casings to replace raw coal in firing boilers, so that there is no need to use raw coal in processing sunflowers, thus saving for the whole year a total of 28,000 tons of raw coal. BRIEFS

ACHIEVEMENTS FOR 1981--1. An overall bumper agricultural harvest was reaped, with a total grain output of 18.34 billion jin and a total oil-bearing crop output of 650 million jin, respectively 7 and 23 percent higher than for the bumper harvest year of 1980, both breaking the previous highest historical levels. 2. A key commodity grain base, Lishu County, on a per capita basis sold over 1,400 jin of commodity grain to the state, and was for the agricultural population of the whole country one of the counties that sold per capita the most commodity grain to the state. 3. The Jilin Chemical Industry Company, getting a tight grip on enterprise reorganization, obtained outstanding economic results. Last year, it overfulfilled ahead of schedule the state plan by 33.2 percent, fulfilling its profit plan. 4. The successful research of technique and equipment by the Jilin Finance and Trade Academy for the manufacture of protein meat from soybean plants has been adopted by over 100 factories in the county, which are now supplying the people with this nutritious food, which is of high quality and low price. 5. With regard to "Jilin's three jewels," which are famous at home and abroad, the amounts of ginseng and pilose antlers purchased respectively increased by 40 percent and over 4 percent over the amounts in the historically highest year of 1980. The amount of sable skin purchased also increased. [Text] [Harbin HEILONGJIANG RIBAO in Chinese 13 Feb 82 p 4]

COTTON GROWING EXPERIMENTS USING PLASTIC SHEET MULCH

Shenyang LIAONING RIBAO in Chinese 31 Jan 82 p 1

[Article: "Remarkable Results from Large Area Experiments Using Plastic Sheet Mulch in Cotton Fields Through Cooperation By Provincial Cotton and Hemp Research Institute, and the Chaoyang, Jinzhou, and Liaoyang Science Commissions"]

> [Editor's Note: More than 2,700 mu of experimental cottonfields have produced ginned cotton yields of from 123 to 172 jin per mu, an increase of 50 to 65 jin per mu as compared with direct sowing, for a between 45 and 113 percent rate of increased yields, opening a new road in the advancement of Liaoning Province's cotton production.]

In 1981 the Provincial Cotton and Hemp Research Institute formed a cooperative team with the science commissions of Chaoyang, Jinzhou, and Liaoyang to conduct large area experiments using plastic sheet mulch in cotton fields in 11 test-site brigades, two communes, and one county, which won outstanding results. From the more than 2,700 mu of cottonfields where plastic sheet mulch was used, yields of ginned cotton ranged from 123 to 172 jin per mu, an increase of from 50 to 65 jin per mu as compared with directly seeded cottonfields, and a rate of increased yields ranging from 45 to 113 percent. From more than 2,400 mu of plastic sheet mulched cotton fields in the Kharchin Leftwing Mongolian Nationality Autonomous County, where rarely encountered high temperatures and draught, ginned cotton yields averaged 123.7 jin per mu, a 65.5 jin per mu increase over ordinary production fields. This pioneering experiment for the purpose of promoting development of cotton production in Liaoning Province paved a new road toward becoming a province that come closer in reaching the goal of producing 100 jin ginned cotton.

The research not only further affirmed the effects of plastic mulch in increasing yields, but also clarified the nature of increased yield effects. From the plastic mulch farming, "three improvements" in cottonfield ecological conditions were introduced, thereby bringing about "three breakthroughs" in cotton farming. The "three improvements" were: First, improvement in the ground temperature conditions in the layer to which seeds are sown and the layer where roots form. Second, improvement in distribution of soil moisture in the cultivated layer, thereby solving the contradiction in the province's cotton growing region between spring drought and the sowing of seeds and protection of seedlings. Third, improvement in soil structure and the chemical properties and light and heat effects in the cultivated layer, creating fine material conditions for promotion of cotton plant growth and development both above and below ground. "The three breakthroughs" were: First, a partial breakthrough in ecological conditions for cotton. Mulched cotton fields had an increase of from 250 to 300 degrees of accumulated heat during the entire growing season as compared with directly sown fields, which solved, to a certain degree, the problem of low spring temperatures, slow growth of young seedlings, and danger from early frost late in the growing season. The growing season was lengthened relatively by from 9 to 15 days, climate resources thereby being made full use of for extremely remarkable results in increased yields. Second was a breakthrough in the progress of cotton growth. After plastic sheet mulch was used for culturing, the progress of cotton growth saw the emergence of seedlings around 5 May, squaring around 5 June, blossoming around 5 July, boll opening around 5 September to lay a foundation for early ripening, high yields, and fine quality cotton. Third was a breakthrough in yields per unit of area. Both the tremendous increase in yields and the degree of consistency from plastic sheet mulch cotton fields was unprecedented. Not only was there a great breakthrough in output from plastic mulch cotton, but the number of flowers before the arrival of frost increased, fibers lengthened, the ginning outturn rate increased, strength increased, and quality improved.

FOOD INDUSTRY DEVELOPMENT URGED

Shenyang LIAONING RIBAO in Chinese 17 Jan 82 p 2

[Editorial: Rapidly Develop the Food Industry"]

[Text] "The people regard food as paradise." The food industry occupies an extremely important position in the lives of the people and the economy of the country. The stability of the nation, the prosperity of the economy, improvement in the life of the people, and the flourishing of tourism all require accelerated development of the food industry.

Since the founding of the People's Republic, the food industry in Liaoning Province has seen considerable development. It already has 18 different industries devoted to the processing of rice and other grain, producing edible oils, reproduction made from the processing of rice and other grains, salt manufacture, sugar refining, making of cigarettes, canned goods, wine making, candies and pastries, condiments, milk products, starch, meat and poultry products, bean products, products made from the processing of vegetables, beverages, edible fungi, flavorings and spices to form a definite foundation and strength for the food industry. However, in terms of the needs of people's livelihoods, demands are still not being met, and quite a gap still exist in comparison with advanced regions of the country. Currently quantities of some food products are inadequate with supply not meeting demand. Products made from beans, name brand fine white wine, and beer in particular, and already popularized supplementary foodstuffs such as soy sauce, vinegar, bean sauce, and pickled vegetables have yet to be supplied widely in rural villages. For a long time children's foods have stagnated in the manufacture of sweetened rice flour powder. Convenience foods universally needed by people, and curative foods still constitute a gap requiring filling. Quality of candies and pastries is not high, and varieties and colors are monotonous, packaging is not done with much taste. Quite a few comrades bring back vermicelli and pastries when they return from trips elsewhere, does this not show that the food industry in this province should rouse itself to catch up?

Liaoning Province possesses numerous advantageous conditions for development of a food industry. Its farm livestock, sideline occupation, and fishery resources are fairly abundant, and the southern and western regions produce

produce fruits, while in eastern and northern mountainous regions, wildlife resources proliferate. The province has a long coastline, and aquatic product resources are also abundant. At the present time, however, these resources are not being fully developed and used. It should also be realized that even though food production in the province is fairly weak, capabilities for development are great; from fermenting techniques to machine processing, and chemical treatment of foods, and large, medium, and small-scale enterprises have been linked together to form a food industry system. There are more than 10 comprehensive and specialized food science research organizations, and results of research appear steadily. If only we will make the most of strengths and make up for weaknesses, rapid development of the food industry is entirely possible.

Requiring solution now is an increase in understanding of the importance of the food industry. The notion that food is nothing but a small matter of eating and drinking and that the heavens will not collapse if no special attention is given to it is mistaken in the extreme. It should be realized that investment required is small, results are rapid and benefits great in the food industry, that it is closely bound up with the lives of the people, and it positively cannot be disregarded. Inasmuch as there are numerous kinds of food industries and numerous trades, and since it cuts across numerous kinds of food industries and numerous trades, and since it cuts across numerous sectors, all jurisdictions should rapidly set up food industry societies to prepare and organize, to make overall plans, and to take responsibility for overall situation. A policy of "unified planning with multiple company managing and push forward combined enterprise" should be adopted. Now is the time for investigation and study to get an understanding of basics and, on the basis of the region's resources and advantages, to set clearly the direction and emphasis for development of the food industry. Looked at the province as a whole, convenience foods, children's foods, beer, beverages, products made from beans, condiments, candies and pastries, famous brand distilled spirits, and curative foods should be the products emphasized for development. All jurisdictions should also give attention to research and readjustment to economic policies that are favorable to the development of the food industry in order to give the food industry more support and financial assistance.

BRIEFS

RECORD COMMODITY SUPPLY--A remarkable increase has taken place in commodities supplied to markets by Liaoning Province's agriculture and light industries, which has strengthened the material foundation of markets. This is a major indicator of the province's economonic development. Last year, the province's agriculture provided markets with agricultural and sideline products with a total value of 3 billion yuan, a more than 50 percent increase over 1980. Products included soybeans, peanuts, fresh fruits, vegetables, the procurement quantities of which increased greatly. Supplies of goods provided markets by the light and textile industries had a value of almost 6 billion yuan, a 7 percent increase over 1980. This included a general increase in products needed in the daily lives of the people. Supply of small commodities and articles used by minority nationalities also improved. There were almost 10,000 designs, colors, sizes, and varieties of goods, and 128 products that are regarded nationally or within the province as fine quality name brands. Increase also occurred in goods brought in from other provinces and goods received through imports. Total output of products supplied to markets exceeded the all-time high to lay a foundation for stabilization of the market and satisfying holiday market requirements. RECORD HIGH FOR LOAN REPAYMENT ESTABLISHED

Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Feb 82 p 2

[Article by Pan Mengyang [3382 1125 7122]: "Ningxia Hui, Han Commune Members Enthusiastically Repay Agricultural Loans: The 1981 Agricultural Loan Repayment Rate Sets Record of 112 Percent"]

[Text] In Ningxia the broad Hui and Han commune members and commune-brigades collectives took the initiative in going to the banks and credit cooperatives to repay agricultural loans totaling over 53.7 million yuan. The agricultural loan repayment rate reached 112 percent, 21 percent higher than last year and a new historical record.

In 1981, Ningxia released 47,850,000 yuan in agricultural loans and recovered 53,710,000 yuan. This reverses the trend of many years in which agricultural loans were issued slowly, in short supply and with unsatisfactory results. This is an entirely new situation in which agricultural loans are issued quickly, are in adequate supply, produce good results and have a quick rate of return. Fifteen of the 18 municipalities and counties achieved a balance in loan recovery in 1981. This was especially true for five counties in Guyuan Prefecture which had been so poor and backward. Last year, the grain crops had reduced production because of drought, so the broad commune members used loans to develop diversified economy, provided for themselves through production and increased their income. They were very grateful to the party and the state and took the initiative in using their income to repay the loans. This prefecture had a repayment rate of 121 percent. The Hui nationality area of Jingyuan County had a repayment rate of 158 percent. Some commune members shook hands with the loan office personnel saying: "If it were not for the loans which enabled us to purchase draft animals and seeds and to improve diversified economy we could never have made so much money. The first thing to do with this money is to repay the state."

BRIEFS

EARLY RELEASE OF AGRICULTURAL LOAN--In order to solve the problem of communes, brigades, and commune members and masses' insufficient funds during spring plowing and production, and in order to plant enough autumn grain and oil-bearing crops to ensure a bumper harvest in agriculture in 1982, the provincial agricultural bank and grain department recently studied and decided to release early the 1982 autumn grain and oil-bearing crop loan for advance purchase deposits of 22.18 million yuan. This is to meet the needs of changes in the rural area production responsibility system. For those production brigades that have already contracted production or work tasks to individual households (groups), contracts must be signed by the households (groups) at the time the loan is released. In order to integrate the release of this loan for advance purchase of grain and oil-bearing crops with the past debts (with the exception of the deposits for advance purchase of wheat last autumn), all areas must carry out well ideological and political work, conscientiously advance further the clearance of past debts, collect those that can be collected, exchange [zhuan huan 6567/2255] [reissue] loan notes for those that cannot be collected temporarily, implement the task of recovering debts and make maximum use of the loan for advance purchase deposits. [Excerpt] [Taiyuan SHANXI RIBAO in Chinese 18 Mar 82 p 2]

GRAIN OUTPUT BUMPER HARVEST--Shanxi Province's total grain output in 1981 was 14.5 billion jin, an increase of 800 million jin or 5.7 percent over 1980. This was the 3rd bumper harvest year since the establishment of the PRC, following those of 1975 and 1979. Of the total grain output, wheat output increased 8.6 million jin over 1980. The autumn grain base output remained the same as 1980's. Oil-bearing crop output in the province was 242 million jin, a decrease of about 9.5 percent compared to the bumper harvest of 1980, which was the highest-yielding year in the province's history. This oil-bearing crop output is the 2nd bumper harvest year since the establishment of the PRC. Sugar beet output in the province was 321 million jin, an increase of 37 percent over the 1980 output. This was the highest level of the province's sugar beet output. This was the highest level of the province's sugar beet output. Tobacco leaf output was 6.48 million jin, twice the 1980 output. As for cotton output, it decreased by 19.4 percent compared to 1980 due to a spring drought and much precipitation in the autumn. At present, rural areas in the entire province are intensifying their preparation for spring plowing in order to achieve an even greater result in agriculture this year. CSO: 4007/377

BRIEFS

ACHIEVEMENTS IN AGRICULTURE, OTHER FIELDS--1. Encountering a flood situation, the likes of which had not been seen in 100 years, agriculture's total output value still increased by 3 percent above that of 1980, history's highest level, among which grain output increased 600 million jin and oil-bearing crop seeds increased over 260 million jin. 2. Over the whole year, 32.5 million pigs were removed from inventory, 19 million pigs were sold to the state and at the end of the year 51.6 million pigs remained in inventory. These three items were among the best in the country. 3. Our country's first high-flux experimental reactor was completed in Sichuan and is operating well. It provides our country with an important medium for developing its atomic energy industry. 4. Chongqing municipality completed the large overhead passenger cableway across the Jialing River. The cableway can transport 1,300 passengers an hour. 5. In Chengdu, our country's largest and best equipped natatorium was completed. [Text] [Harbin HEILONGJIANG RIBAO in Chinese 13 Feb 82 p 4] 9727

PROMOTION OF SCIENTIFIC FARMING AT GRASSROOTS LEVEL PUSHED

Kunming YUNNAN RIBAO in Chinese 2 Feb 82 p 2

[Article by Li Daoping [2621 6670 1627]: "Use of Diverse Methods to Promote Agricultural Science and Technology"]

[Text] Jinggu Commune in Jinggu County is a commune in a semimountainous area that grows both grain and tea. In 1981, the commune's grain output totaled 10 percent more than during the previous year, and quantity of tea procured was 20 percent more than during the previous year. Aside from its implementation of policies and the fine weather, the reason for Jinggu Commune's harvest of bumper crops of both grain and tea lay in promotion of agricultural science and technology. In 1981, this commune did the following in the way of introducing and promoting agricultural techniques.

1. It set up science and technology households. Scientists and technicians selected from among Jinggu, Tuanshan, and Yunpan brigades several commune members who believed in science and who had experience in production. After gaining their agreement, these were designated science and technology households with responsibilities for promotion of advanced technical experiments and demonstrating subjects. Following a period of technical training, the 98 science and technology households in the three production brigades assumed responsibility in conjunction with farm scientists for experimental projects in the introduction of superior varieties of rice, tea, and wheat, with startling results. Commune member Ji Wenxue [4764 2429 1331] of Tuanshan brigade was responsible for the introduction of experiments on a new variety of glutinous paddy, his 0.7 mu producing 640 jin of glutinous paddy. Ji Wenxue said happily, "I want to be a science and technology household again next year to promote more new techniques and new superior varieties here."

2. It launched consultation services. In order to do a good job of farming on fields for which production had been contracted, commune members frequently sought the advice of farm scientists on agricultural science and technology. The commune farm science station set up a special consulting service project, and any commune member who came to its doors seeking instruction was given an answer on the spot. At the place that sold pesticide in the supply and marketing cooperative, farm scientists Li Dayun [2621 1129 7189] taught commune members how to mix and use pesticides. During the year, the farm science station answered questions for 1,000 people. For commune members who were still unable

to understand techniques after having been given an explanation on the spot, the farm science station wrote out a "prescription," writing on a piece of paper in everyday language a detailed explanation to the question that the commune member had asked. Another method the consultative service used was to go to households and give practical help to commune members in solving difficulties with technology.

3. It promoted systems of responsibility linking science and technology to output. Last year, the technicians and commune members of six households in this commune signed a farming contract for a bumper rice harvest following the wheat harvest, and the technicians signed a contract with 11 commune member households for the specified growing of corn and wheat. Results of these agreements were that, except for one household that diverted to another field the fertilizer that the farm science station had invested in a field linked to output and another household that suffered a reduced output because it omitted to use insect spray, the other 12 households had increases in output, and three households maintained the outputs that they formerly had had. Both the farm science personnel and the commune members benefited. Now more commune members have entered into agreements with the farm science station for growing of bumper harvest of rape and bumper harvests of early millet.

While promoting agricultural science and technology, Jinggu Commune also attended to science popularization and propaganda work. They used blackboard newspapers, charts, propagandizing on the streets, and the running of training classes to introduce general knowledge of agricultural science to the masses, and to train a group of mainstay science and technology cadres. Now the commune has more than 160 mainstay science and technology cadres, all of whom have mastered a certain amount of knowledge about agricultural science, who are the commune's leaders in scientific farming.

MEETINGS ON AGRICULTURAL PRODUCTION RESPONSIBILITY SYSTEM HELD IN KUNMING

Kunming YUNNAN RIBAO in Chinese 12 Dec 81 p 1

[Article by Yu Zhi [3768 6347]: "National Agricultural Production Responsibility System Discussion Meeting Held in Kunming"]

[Text] A national meeting to discuss problems on agricultural production responsibility system was held in Kunming on 9 December.

This discussion meeting was jointly convened by the Institute of Agricultural Economics of the Chinese Academy of Social Sciences and the Yunnan Provincial Academy of Social Sciences. Participants in the meeting were experts, scholars and comrades in positions of responsibility and doing practical work from the Chinese Academy of Social Sciences and affiliated units, and from all province, municipalities and autonomous regions totaling 110 persons.

The main purpose of this meeting was to study and explore the new situations and new problems that had arisen following the practice in rural areas of a system of responsibility for production. This included matters such as problems in the evaluation of the system of fixing output quotas for individual households and assigning households full responsibility for task completion; how to accurately understand and grasp the problems of both collective management and the contract system and the problem of combining collective management with the contract system; how to correctly evaluate new collective economy of different forms through peasants' initiative and its problems in the development and future; and how the rural management system should carry out restructuring while adhering to the principles of "two long-term constant": no changes for a long period of time in the system of public ownership of land, and no changes for a long period of time in responsibility system. Application of the fundamental principles of Marxism-Leninism, analysis and study of these new problems, and working out suitable solutions were tasks proposed by this meeting.

INCREASED TEA PRODUCTION BENEFITTING STATE, PEASANTS

Hangzhou ZHEJIANG RIBAO in Chinese 3 Feb 82 p 1

[Article: "Increased Tea Production Can Benefit the State and Peasants With Greater Incomes--Zhejiang Province Inaugurates a Policy of Setting Quotas for Tea Procurements With Higher Prices for Over-Quota Sales"]

[Text] In 1981, Zhejiang Province continuously pursued the policy of setting tea procurement quotas with higher prices for over-quota sales. This policy can lead to four advantages: promotion of tea production and procurements, higher profits for tea processing plants, more benefits for peasants growing tea, and greater financial accumulation for the state.

First of all, the policy of setting quotas for tea procurement and higher prices for over-quota sales stimulates the initiative of tea production by tea-growing peasants and communes and production brigades in tea-producing areas. In 1981, tea production in Zhejiang Province was about 1.72 million piculs, more than 10 percent over the amount in 1980. Tea procurements in 1981 were 1.56 million piculs, 15 percent over the amount in 1980. Both 1981 production and procurement figures are the highest in history. In 1981, peasants sold the state 540,000 piculs of tea over the quotas with higher price income of 23.31 million yuan, an increase of 10.21 million yuan over 1980.

The tea-producing counties have an overall political view and see the entire situation. They supplied the state-operated tea processing plants with abundant raw materials--tea leaves procured from peasants. The tea processing plants adopted means to encourage over-quota sales and to return most processing profits to the counties supplying the over-quota tea leaves. In 1981, the total returned profits to the counties supplying tea amounted to 4.08 million yuan; the amount was exclusively used to support tea production. In 1981, the various state-operated tea plants earned an over-quota profit of an additional 680,000 yuan more than in 1980.

The state also had a corresponding gain in financial accumulation from increases of volumes in tea production, processing and sales. In 1981, the tax revenue income to the state treasury due to tea procurement was 75.37 million yuan, 4.26 million yuan over 1980.

USE OF ORGANIC FERTILIZER TO ACHIEVE BUMPER HARVESTS URGED

Hangzhou ZHEJIANG RIBAO in Chinese 9 Feb 82 p 1

[Editorial by Zhen Xiazheng [7115 2556 1794]: "Present Composition of Fertilizers Hampers Increase in Agricultural Output Since Organic Fertilizer Should Be Stressed to Achieve Bumper Harvests"]

[Text] Crops require fertilizer as food, so adequate fertilizers should be available in preparation for plowing.

This year the complaint of "fertilizer shortage" was heard in many localities; however, some people noticed that no commune members came to cities to collect garbage from street and lane residents. Very few peasants still blend soil with ash from straw. No peasants fight to collect feces and urine in the cities....Look at the statistical tables of agricultural departments: the 1981 cultivated area of green-manured crops in Zhejiang Province was reduced by more than 600,000 mu. A shortage of grass seeds was projected but there is an inventory of 5 million jin. This is an abnormal phenomenon. If there is a shortage of fertilizer, why is this fertilizer source overlooked?

Some comrades who are aware of the situation in the rural areas pointed out that at present people yearn only for chemical fertilizer. Urea and ammonium sulfate are needed, the more the better. It seems that organic manure is out of fashion.

This is reallly an alarming and mounting trend. The proportion of organic manure used by peasants is steadily declining. In some areas only 20 to 30 percent of fertilizer is supplied by organic manure but there are cases where hundreds of jin of chemical fertilizer is applied annually per mu of farm field. What is the result if only chemical fertilizer is applied? Let us look at some facts from recent years.

First, crops are deficient in nutrition so their growth is retarded, causing low outputs. Just as a person needs different nutrients from different foods, a crop needs more than ten types of nutrients during its growth process. Organic manure is a complete fertilizer, containing not only the three major elements (nitrogen, phosphorus and potassium), but also minor elements like calcium, magnesium, sulfur, and iron, as well as trace elements like boron, manganese, copper, zinc, molybdenum and silicon to meet a crop's requirements.

At present, the reduction in organic manure reduces the amounts of some nutrients required by a crop. This imbalance in nutrients leads to nutrition-deficiency diseases. The flowering of rape without bearing seeds is a symptom of boron deficiency. At the beginning, the boron-deficiency disease only occurred in one or two counties, but now rape crops planted in 32 counties suffer from this deficiency, necessitating boron spraying onto an area of 1.5 million mu, occupying more than 43 percent of the total rape cultivation area in these counties. Because of the boron deficiency, cotton plants grow buds but not flowers; wheat plants bear no grains in empty hulls. Moreover, orange trees suffer from a deficiency of iron and manganese; paddy rice plants are deficient in zinc and silicon; and cotton plants suffer from potassium deficiency. More and more severe situations are developing. According to statistics from four counties (Cixi, Shangyu, Xiaoshan, and Haiyan), more than 170,000 mu of cotton plants suffered from stem blight in 1981 due to potassium deficiency. Cotton harvests were reduced by 10 to 20 percent.

Secondly, crop pests are spreading. Crops relying mainly on nitrogen chemical fertilizer have lower pest resistance and contract diseases more easily than those treated with organic manure. This was the situation in recent years. Using specialized terminology, this is an increase of non-protein nitrogen and weakening of pest resistance. According to information from comrades in agricultural departments, in recent years there were wide outbreaks of stripe rust disease, leaf blight and spot, and spike-neck pests. Although these outbreaks are related to meteorological conditions, yet higher pest rates, wider outbreak areas, and more serious diseases occurred in regions with heavier applications of chemical fertilizer than other regions. From data provided by Yinxian County, according to studies of 50 plots of late-maturing rice fields in 1980, with heavier application of chemical fertilizers, in indexes of leaf blight and spot were correspondingly higher and outputs lower. In that year, 1980, there was 245,000 mu of early maturing rice fields suffering from the outbreak of leaf blight and spot; the loss of grain amounted to 38 million jin.

Thirdly, the soil crusts over and fertility declines. New low-output fields are appearing. According to studies both at home and abroad, approximately 70 percent of crop nutrients are derived from the soil, therefore land cultivation requires maintaining soil fertility, thus requiring the application of organic manure. With reduced application of organic manure, soil fertility is not replenished after exhaustion, thus causing lower harvests. For example, of the cotton harvests in Cixi County, in the past, areas planted to green-manure crops amounted to 80-90 percent; later the percentage gradually dropped to under 15 percent. Moreover, a smaller number of hogs were raised, resulting in less barnyard manure. Year after year, chemical fertilizers were mainly relied upon, resulting in continuously decreasing organic matter in the soil. According to surveys by the Zhejiang Provincial Academy of Agricultural Sciences, in 3 years the reduction of organic matter in cotton fields is 10 percent if no green manure crops are planted. At present, about 79 percent of the cotton fields in Cixi County suffer deficiency or serious deficiency in organic matter. Year after year of cultivation has led to greater and greater soil crusting; the cotton yields were reduced to about 70 jin from more than 150 jin per mu. As some commune members said, "how can you expect a bumper harvest if cotton is planted on hard-surfaced highways?"

Additionally, there are abnormal changes: thinner blades of mulberry and tea leaves, diluted flavors in melons and fruits, lower quality of rice grains, and smaller cotton bolls; every one of the abovementioned phenomena is related to the shortage of organic manure.

We can see that good crop harvests cannot be obtained by applying less organic manure. We stress organic manure: this is not a temporary measure to solve the fertilizer-shortage problem. This is a strategic plan to ensure high and steady crop harvests with high quality and low cost.

There is a farming proverb in Zhejiang Province, "Two types of valuables in farming: hog manure and safflower." Viewing only the immediate and temporary economic benefit, some people believe that cultivation and the accumulation of manure are not as good as simply buying fertilizers. They discard these two valuables; this is an incorrect policy. Some other peasants receive endless benefits only understanding these valuables. Since the development of duckweed cultivation in paddy fields from 1979 on at Taoshan Ward of Rui'an County, the annual increase of grain output has been more than 100 jin per mu. The Lujiawan Production Brigade in Deqing County and Zhongan Brigade in Tongxiang County had for the past 6 or 7 years a per mu output of more than 2000 jin of grain. Not only were bumper harvests obtained in grains and mulberry leaves, but also high and steady production of fish raised in ponds. One of their primary conclusions is the application of large amounts of barnyard manure, river mud, and miscellaneous soil-blended manure, as well as returning to the field of rice straw and wheat stems. Each year, the return and renewal of organic matter to the farm field amounted to 2000 jin per mu. Hence, soil fertility was increased with greater cultivation. As always, yields of late-maturing rice in Zhejiang Province have not been high and steady. However, in these two brigades the per mu yields of late-maturing rice amounted, respectively, to 910 and 966 jin. This is a good example showing that fertile soil leads to bumper harvests.

At present, more and more countries recognize the importance of applying more organic manure. In recent years, a large number of people were sent from abroad to Zhejiang Province to learn about what has been achieved in applying organic manure; some people even stayed for a long period to study the cultivation of duckweed in paddy fields. In 1981, the Soil Resources and Protection Section of United Nations FAO organized experts from 11 countries in the Asian Pacific area to visit China to study the utilization of green manure. Engaging in many years of "inorganic farming," these countries now stress organic manure. Why do we, traditionally stressing organic manure, conversely now discard the organic manure?

This is the reason why the agricultural experts have been demanding the use of organic manure in farming.

AGRICULTURAL BANK SUPPORT TO COMMUNE, BRIGADE ENTERPRISES

Hangzhou ZHEJIANG RIBAO in Chinese 28 Jan 82 p 1

[Article: "1981 Loans of 1.4 Billion Yuan to Commune and Brigade Enterprises by Agricultural Banks in Zhejiang Province--Support the Commune and Brigade Enterprises to Develop Production of Consumer Goods by Utilizing Local Resources"]

[Text] According to the policy of national economic readjustment, different levels of agricultural banks and credit unions of Zhejiang Province granted loans of 1.4 billion yuan to commune and production brigade enterprises to support them in the development of consumer goods production by adequately utilizing local resources.

Last year cadres of agricultural banks and credit unions of some regions of the province toured rural areas to investigate and study more than 30,000 commune-and production brigade-operated enterprises. According to the production, supply and sales trends of products as well as the management and administration situations of these enterprises, the banks and credit unions selected enterprises with outstanding performance for priority handling to support the production of consumer goods in heavy demand, as well as the processing of agricultural and sideline products and the production of small farm implements. In Haining County, in 1981 the agricultural banks and credit unions granted loans of 70 million yuan to commune-and brigade-operated textile industries and agricultural and sideline processing industries. These loans promoted the development of commune and brigade enterprises with a total production of 193 million yuan, 45 percent over 1980.

In order to help commune and brigade enterprises to increase economic benefits, many municipality and county bank branches stressed economic information activities by helping these enterprises to have timely access to changes in supply and demand. By tapping the advantageous conditions of wide-ranging connections of financial department, the banks in different localities open sales and purchase channels to help enterprises to handle inventory and production goods. Moreover, by using the means of settlement, the banks helped in promptly recovering receivables, thus speeding up capital circulation in enterprises.

BRIEFS

LIVE HOG PROCUREMENT QUOTA FULFILLED--Up to 10 March 1982, Zhejiang Province has already procured 2.38 million head of live hogs, thus fulfilling early the first quarter of procurement quota. This is a 6.8 percent of increase during the same period in 1981. Since the beginning of 1982, government of all levels has strengthened the leadership in live hog production, focusing its policy on stabilizing commune- and brigade-run live hog production and the state's procurement task. I. GENERAL INFORMATION

PEP TALK GIVEN IN PREPARATION FOR ANOTHER YEAR OF ACRICULTURAL ACTIVITY

Beijing ZHONGGUO NONGMIN BAO in Chinese 7 Feb 82 p 1

[Article by Commentator: "Strive to Increase Economic Benefits from Agriculture"]

[Text] The lunar new year has come and gone, and soon spring plowing and production, and spring production activities in forestry, animal husbandry, and the fishing industry will move from south to north. Consecutive years of bumper harvests and bumper earnings in many places have provided extremely advantageous conditions for this year's production, if agricultural production is to maintain all-around development during this new year, special attention will have to be given to broadening avenues of production, lowering production expenses, and increasing economic benefits.

Striving for economic benefits is something that agricultural production and other production units should give extreme attention. In the farming industry, the breeding industry, and rural industrial sideline occupations, emphasis should be given increases in yields per unit of area, to improving quality of products, to raising labor productivity rates and commodity rates, and to getting maximum economic benefits from minimum investment of labor and capital. The former practice in agricultural production of not striving for benefits, not being concerned with economic acounting, extravagance and waste, and increase output without increasing earnings should not be repeated.

In striving for economic benefits, one cannot look only at momentary increases in individual economic benefits, but rather simultaneously take into consideration longrange many sided overall economic benefits. For the present, this means having the state plan paramount and market regulation supplementary in the formulation, in combination with local conditions, of production plans for the entire year. There has to be all-around implementation of the program of "positively no relaxation of grain production and active development of economic diversification," and making the most of local advantages, and development through adaptation of general methods to local situations had to be coordinated with an equitable pattern nationally to prevent a tendency toward blind production and sole pursuit of profits that is deleterious for the working people's wealth. In matters such as stability of the area sown to grain, implementation of production plans and a bonus system for hog raising, and suburban vegetable production, equitable arrangements have to be made. Planned procurement of agricultural sideline products by commercial units must be on the basis of contracts concluded with production brigades and communes that are jointly honored.

Pursuit of economic benefits requires very good arousal of the enthusiasm of producers. Today, more than 90 percent of all rural production teams practice various forms of a system of responsibility in which contracting is linked to production. When peasants plant crops, raise livestock, or engage in industrial sideline occupations, costs must be taken into account, and careful calculations made. Management and administration has to be improved in an effort to increase economic benefits. This requires, in advance of spring production, that the forms of a system of responsiblity for production be stabilized as quickly as possible, and that various forms of contracts be concluded setting forth the economic relationships and the rights and obligations of production teams and commune members, and among work teams, permitting production teams and commune members to do early planning, and act early in order to assure realization of economic benefits.

Pursuit of economic benefits requires vigorous extension of science and technology, equitable use of resources and investment, and fullest use of the role of rural scientific and technical personnel. This includes equitable use of land, pastures and water surfaces; adaptation of general methods to local situations in the selection of superior varieties, arousal of the masses to select breeds and process seeds to improve farming and livestock raising techniques; to fertilize scientifically, and to use pesticides and water scientifically; and to select machines and implements for the farming, forestry, livestock raising, and fishing industries, etc. The broad masses of people, cadres, and technicians must also be depended on for the establishment and perfection of systems of responsibility for extension of technology so that greater benefits will be derived from the enthusiasm for study and use of science that is building in rural areas.

Pursuit of economic benefits also requires intensification of ideological and political work. Party organizations at every level, and cadres at every level in rural areas are to indoctrinate the broad masses of peasants in the need to act on the principal of the whole nation being a chessboard, giving consideration to the welfare of the country, the collective, and individuals rather than caring only about oneself. Simultaneous with active peasant support to cities and to industrial construction, each trade and industry should vigorously support agriculture. Units concerned should promptly provide rural villages the high quality and low priced means of production needed for spring production so that agriculture can better bring economic benefits into play.

Improvement in economic benefits is a longrange task. However, attention must be given to action from the very beginning of the year, and action must be taken regularly, firmly, and totally. Cnly in this way can genuine economic benefits be brought about.

PERFORMANCE, PROSPECTS FOR FISHING INDUSTRY DISCUSSED

Future Emphasis in Three Areas

Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Feb 82 p 2

[Article by Xiao Peng [5135 7720], State Aquatic Products Administration]

[Text] During 1981, the broad masses of staff and workers in the aquatic products sector have rallied to produce rather good achievements in the development of China's aquatic products enterprises. Nevertheless, both quantity and quality of aquatic products are still a very long way from satisfying the ever increasing needs of the people. During the coming year of 1982, we need to do a great deal of work in many fields, notably the following three.

First is continued implementation of the program of readjustment of aquatic production, hastening development of both freshwater and ocean breeding. During the past several years, the breeding industry has increased by about 10 percent annually, an unprecedented accomplishment. Recently CCP Central Committee leadership comrades have noted that economic diversification requires emphasis on making the most of the potential that water surfaces and beaches around bodies of water provide to add new impetus to development of the hatching of aquatic products. We are determined to take the opportunity to maintain and develop this fine momentum, relying on policies and on science to do a solid job of solving problems with fry, with feeds, with fish diseases, and with efforts to promote key techniques. In ocean fishing, the measures to protect resources taken during the past several years and the results achieved must be consolidated. At the same time, it is necessary to actively develop economic diversification, to assemble high horsepower fishing boats for deep sea production, to make use of everything in processing, to upgrade quality and output value in every way, and to provide for surplus labor in fishing areas.

Second is use of every available means to improve economic benefits. In the breeding, catching, production, supply and marketing of aquatic products, both state-owned or collectively-owned, potential for increase in economic benefits is very large. China's traditional fish raising methods which are linked to farming, forestry, and livestock raising, are world renowned for their advanced techniques of making full use of resources, conserving energy, and maintaining ecological balance; however, through the use of modern scientific methods to solve problems with mixed feeds and the breeding of fine varieties, economic benefits can be further improved greatly, to say nothing of what these techniques can do for places that "raise fish in plain water and rely on heaven for results." A priority task is to devise ways in which minimum expenditures can bring maximum benefits in situations in which resources are not good for catches or where energy is insufficient... The enthusiasm among the broad masses of fishermen that institution of systems of responsibility for production by fishing communes and brigades has aroused should increase economic benefits. The reorganization of teams in state-owned aquatic products enterprises and the improvements made in administration and management have as their goal increases in output and effecting savings. Equipping of the commodity bases, whose construction the state has supported during the past several years, should be emphasized to derive benefits from investment. In short, emphasis should be placed on going into production to increase economic benefits, with implementation in every field for the building of aquatic products production.

Third is intensification of ideological and political work, indoctrinating the broad masses of fishermen, staff and workers in a conscious proper relationship among the interests of the country, the collective, and the individual. The policies instituted since the Third Plenary Session [of the 11th Party Central Committee] whereby procurement prices paid by the state for aquatic products have been increased and a combination of requisition procurement and negotiation procurement has been put into effect have substantially increased fishermen's earnings. In the present situation of a shortage of aquatic products and great list price differences, indoctrination of fishermen should emphasize selling more fish, selling good fish, and making sure that quotas for sales to the state are fulfilled to make a great contribution to the country. In addition, attention should be directed to correcting a tendency in some communes and brigades to strive for increases in earnings to the neglect of collective accumulations. In communes and brigades and in enterprises in fishing regions, there should be continued adherence to resisting and opposing various unhealthy tendencies, and active building of socialist spiritual civilization.

Increase in Cold Storage Facilities

Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Feb 82 p 2

[Article by Chen Xiaojun [7115 2556 6511]]

[Text] In 1981, the broad masses of fishermen, staff and workers in fishing industry communes, brigades and enterprises throughout the country conscientiously put into effect a program of readjustment for equitable use of resources, vigorous development of breeding, and improvement in quality of products. Planned output of aquatic products for the year was for a five percent increase over 1980, and preliminary statistics show that production plans are likely to be overfulfilled by five percent. The addition of 36,000 tons of cold storage capacity makes 1981 the greatest year of increase since founding of the People's Republic.

Freshwater fish raising increased by more that 10 percent over 1980, and state-owned and collective water surfaces for the raising of freshwater fish increased by 2 million mu over 1980. Commune member household raising of fish has also been ever greater. According to incomplete statistics from six provinces including Hunan, commune household raising of fish has already passed the 1.2 million household mark on water surfaces of somewhat more than 360,000 mu. A water surface area of somewhat more than 230,000 mu where commodity fish bases have been built with state support have gone into production, an increase that more than doubles the 1980 amount. Statistics from 106 large and medium size cities report quantity of fish raised in suburbs to have risen from 100,000 tons in 1979 to more than 150,000 tons.

Thanks to institution of rights to beach areas and systems of responsibility for production, which aroused enthusiasm in all quarters, the ocean breeding area increased 10 percent over 1980 and output overfulfilled plan by 10 percent. Sea delicacies and mollusks found in shallow-water areas were particularly productive. Despite the rather severe disasters that beset shrimp breeding in 1980, output still overfulfilled plan.

Ocean fishing industry adoption in recent years of measures to protect propagation of resources has turned around a tendency toward decline of some kinds of fish, as for example, hairtails in the East China Sea, which have provided bountiful harvests for 2 consecutive years. All-around use of off-shore fishing has begun, and active development of deepwater fishing is underway, deepwater catches having increased by 25 percent over 1980.

As a result of the growth in fishing industry production, average per capita income for fishermen in 1980 amounted to 173 yuan, and it is predicted that 1981 figures will also show an increase to have occurred. In some places, extent of increase has been tremendous. The Tianjiaweizi Fishing Brigade in Gai County, Liaoning is one such place where during 1981 accumulations increased 2.9 fold; commune member earnings averaged more than 1,000 yuan per capita, and the collective's total earnings increased 2.1 fold over 1980.

EXCESSIVE CONTROL OF TOBACCO CRITICIZED

Beijing RENMIN RIBAO in Chinese 19 Jan 82 p 2

[Article by Yang Guoan [2799 0948 1344]: "How Can Flue-cured Tobacco Procurement and Sales Adapt to Growth of Production? Last Year Produced a Bumper Crop of Flue-Cured Tobacco For a 9 Million Dan Surplus Nationally, Yet Some Marketing Areas Continued to Import Tobacco While Producing Had a Serious Glut on Hand"]

> [Text] Editor's Note: Following publication of a column discussing "How Can the Circulation Field Adapt to Rural Economic Growth?", we received some letters from readers expressing their gladness about and support for the discussion. Columns printed during the past several weeks have presented some different views on the issue of the relationship among requisition procurement base figures, plan channels, and other channels for the start of a discussion. The two articles printed today are also related to the above issue. We welcome readers everywhere, particularly comrades doing grassroots work, to send in letters to jointly make the discussion of this column more thoroughgoing.

Flue-cured tobacco is one of China's major economic crops. As a raw material for a consumption good used in a habit, tobacco has only one use, unlike grain for which the greater the production the better. Consequently, production of flue-cured tobacco must be linked to demand.

For many years a conspicuous problem in the development of flue-cured tobacco in China has been that production has been out of line with demand. Production has been blind, tobacco being momentarily in plentiful supply only to be momentarily in short supply, placing both the cigarette manufacturing industry and tobacco production in a passive role. At the present stage, China's flue-cured tobacco output cannot be said to be very great, but it is changing away from being a commodity in short supply. If the relationship beween production and needs is not handled well and blind development takes place, inevitably we will have to rewalk the old road of ups and downs in supply.

Commodity circulation is the bridge that links production with consumption. In order to adapt to the present rural economic situation and promote planned and stable growth in China's flue-cured tobacco production, circulation links must solve the following real problems.

(1) Organizing and guiding production on the basis of social needs. In both quantity and quality, tobacco production must be generally commensurate with market demand. In this matter, full investigation and study and market surveys are extremely important. Reliable market information must be regularly supplied producers so that they know what's what and can scientifically plan and arrange for development of production. The simple method of "cutting when there is too much and catching up when there is not enough," is not a good means for actively organizing production and circulation.

(2) Use of economic agreements to dovetail industry and commerce and agriculture and commerce. First, under plan guidance, there should be organization of production (areas) and marketing (areas) by vocational units in charge for direct contacts and formulation of supply and demand contracts between units dealing in tobacco and cigarette enterprises. Next, on the basis of needs, units dealing in tobacco should make procurement and marketing agreements with tobacco producers, and organize tobacco production in coordination with agricultural units, put into effect acreage and sales quantities, and propose quality requirements. Procurement units would have to guarantee to buy the quantities stipulated in the agreements, while at the same time taking necessary economic measures or placing limits on those who do not live up to agreements or plant blindly.

(3) Improvement in methods of allocating supplies. Under the present system whereby units in charge, from top to bottom, uniformly distribute tobacco instead of allowing market trade, not only are links and layers more numerous, but control is stifling. When commodities are somewhat greater than usual, if plants do not actively order them, commercial units feel they have to carry a burden. When commodities are a little less than usual, and cigarette plants have trouble getting an allocation, people are out everywhere trying to buy tobacco. In 1981 flue-cured tobacco output increased tremendously and national production and demand were in balance for the year with a surplus of about 3 million dan. However, owing to the restriction of administrative controls in the allocation of tobacco, the increase in output did not mean an increase in allocations. On the one hand in some marketing areas supply of raw materials to make cigarettes were insufficient and tobacco was steadily imported, while on the other hand there was a serious glut in producing areas, some tobacco being lost through mildewing and rotting. The key to change in this situation lies in adherence to a planned economy and making full use of the supplementary role of market regulation, with the gradual establishment of a liberalized commodity circulation market including direct signing of economic contracts between both parties to supply and demand under guidance of the state plan.

TWO NEW COTTON VARIETIES COMPARED

Beijing RENMIN RIBAO in Chinese 19 Jan 82 p 2

[Article by Zhong Haozhang [6988 3185 4949], Cotton Institute, Chinese Academy of Agricultural Sciences, "What Is the Difference Between Zhongmiansuo No 8 and Zhongmiansuo No 10 Cotton Varieties?"]

[Text] On 2 May 1981 your newspaper carried a story on fine cotton variety, "Zhongmiansuo No 8," and subsequently carried another article on "Zhongmiansuo No 10." Now I will reply below to the several letters your newspaper forwarded from readers inquiring about the differences and characteristics of these two varieties.

"Zhongmiansuo No 8" strain (formerly known as 758), is a hybrid formed from 24 - 21 x [(e1472 x Mian 6-11) x 5476N] through the continuous breeding of individual plants, which was successfully produced in 1976. In an average year it has a 135 - 140 day growth period, making it an early maturing intermediate upland cotton variety. Plants reach a height of from 80 to 110 centimeters. Sowing may be done in spring, the period between 15 and 25 April being the most suitable time for sowing. Density per mu of seedlings should be as follows: 4,000 plants per mu in most cottonfields. For high yield fields producing more than 220 jin per mu of ginned cotton, 2,500 to 3,500 plants should be retained, each plant keeping 11 to 15 boll-bearing branches. This variety's greatest merit is its high ginning outturn rate, and its stability. Ginning outturn averages 42 to 46 percent, and reaches a maximum of 48 percent. Because of the high ginning outturn rate, yields of ginned cotton per unit of area are also high. Results of experiments in regional testing of cotton varieties at 17 sites in the cotton growing area of the Huang He basin showed, for example, yields of ginned cotton averaging 193.21 jin per unit of area, 18.8 jin more than for the control variety (Lumian No 1).

"Zhongmiansuo No 10" (formerly 509). This strain was bred from a natural variant, "Heishanmian No 1," and it is an early maturing upland cotton variety. Its total growing period is 113 days. Plant height is about 50 centimeters. It is suitable for growing in a continuous two crop changed farming system. It should be sown in early June. About 8,000 plants per mu should be retained.

Because the period for boll formation is short when cotton is grown following wheat, boll formation on individual plants is relatively small. In order to get high output, density of planting has to be increased, planting has to be done early and pushed up the earth correctly, so that between 5 and 6 boll-bearing branches can be retained on each plant. This variety's greatest merits are early ripening, bumper yields, and superior quality. Results of regional tests at 12 test sites in the Huang He basin in 1980 showed, for example, yields of ginned cotton averaging 138.1 jin per mu, 30.8 jin more than from "Heishanmiao No 1."

This shows that the two varieties differ greatly. The growing season for "Zhongmiansuo No 8" is relatively long; it is suitable for spring planting; and it requires sparse planting. The growing season for "Zhongmiansuo No 10" is short; it is suitable for summer planting; and it requires dense planting. Each has its own individual characteristics and properties, and its own environmental and planting requirements. Furthermore, the two varieties differ also both individually and in colonies.

FINE SHOWING REPORTED BY STATE FARM DESPITE CALAMITIES

Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Feb 82 p 1

[Article by Yu Xin [0060 2450]: "State Farm and Land Reclamation System Triumphs Over Calamities to Win Heartening Achievements in Production in 1981"]

[Text] In 1981 the national state farm and land reclamation system triumphed over serious natural calamities and, except in Heilongjiang reclamation areas where particularly severe flooding reduced grain outputs, a slight surplus for the year is expected after profits have been offset against losses throughout the system, with cotton output increasing by 23.8 percent, oil-bearing crops increasing by 14.4 percent, sugar crops increasing by 9.5 percent, dry rubber increasing by 1.3 percent, tea and fruit increasing by about 6 percent, and industrial output value increasing by 10 percent.

In 1981, 44 percent of the national state farm and land reclamation system's total cultivated land area sustained disasters. This included 80 percent of the sown area in Heilongjiang's reclamation areas where 33 percent of crops were lost. Lashed by such serious catastrophes, the state farms took firmly in hand readjustment of the orientation of investment, the economic structure, and crop patterns, winning rather good economic results for their efforts. In the Xinjiang reclamation areas, grain, cotton, and oil-bearing crop outputs reached all-time highs for a reversal of 12 years of continuous losses. Farms and industrial plants under the Jiangsu State Farm and Land Reclamation Bureau made a profit.

Simultaneous with attention to implementation of systems of responsibility for production and widening of production avenues, plus development of economic diversification, the state farm and land reclamation system actively developed integrated agricultural, industrial, and commercial operations. In 1981, numerous prefectures carried on liaison outside the prefecture to open commercial channels and develop markets for products. In Henan, 67 percent of farms experimented with integrated enterprises, building more than 200 network outlets for anticipated profits of 800,000 yuan. The state farm and land reclamation system also showed extreme concern for technical training. The Yunnan Agriculture and Land Reclamation Administration alone ran 50 cadre training classes with 4,460 enrollments for study. The state farm and land reclamation system also devoted intense attention to scientific farming, and did a lot of work in soil improvement, in increasing soil fertility, in preventing and controling diseases and insect pests, and in promoting fine varieties and new techniques, which produced remarkable results. One example was in Xinjiang reclamation areas where promotion of the new techniques of using plastic sheet mulch in the growing of cotton increased cotton output by from 35 to 50 percent.

LAXITY IN SOME GRASSROOTS ORGANIZATIONS SCORED

Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Feb 82 p 1

[Article by Commentator: "Conscientiously Surmount Laxity in Some Rural Grassroots Organizations"]

[Text] How to maintain the paramount position of the collective economy in the process of summarizing and perfecting rural systems of responsibility for production, make the most of the economic function and the function of political power of communes and brigades, and surmount a troublesome situation of laxity in grassroots organizations in some communes and brigades in which no one looks after the collective economy and no one takes responsibility for building production are problems in urgent need of solution.

Currently China's rural economy has both a collective economy in which the scale of organization varies and methods of operation differ, and also state farms and a household economy that augments the collective economy. Such a diversified economic structure both helps give impetus to more rapid development of social productivity and helps take full advantage of the superiority of the socialist system. However, China is a socialist country with a population of 1 billion that both has to provide food for its people and also has to smoothly carry out socialist construction. This requires practice of a planned economy on a foundation of public ownership while, at the same time, bringing into play the supplementary role of market regulation. The rural commune and brigade collective economy is the tissue cell of China's planned economy, and the forward base for the acceleration of agricultural growth and realization of the modernization of agriculture. Under the new situation of practice of various forms of a system of responsibility for production, rural communes and brigades perform an economic function in the collective economy, which not only cannot be weakened but rather requires constant improvement and strengthening. This is the only way to meet the new situation in development of agriculture, to provide for production, and to organize market sales so that China's agriculture, from production to marketing, is conducted under the guidance of state plans, thereby satisfying requirements of both the state plan and urban and rural markets.

With the establishment of systems of responsibility for production, as a result of improvements in the organization of labor and methods of calculating remuneration, and the coordination of the relationship between collective welfare and individual welfare, enthusiasm for both unified collective farming and independent farming by workers has been aroused. In consequence, some people suppose that with "a fixing of output quotas on a household basis, [which] makes every family its own cadres," production needs no longer be arranged by the collective, and the economy no longer needs be controlled by the collective as though the economic function of rural communes and brigades had disappeared. In addition, some rural cadres are momentarily puzzled about party policies and do not know how to function under these new circumstances. They do not dare exercise control over matters that destroy collective property, and they do not dare oppose dishonest practices. As a result, grassroots organization in some cummunes and brigades is lax or has devolved into a state of paralysis or semi-paralysis. This is highly irregular and unnecessary.

It should be explained that with the establishment of systems of responsibility and the dispersal to individual households of certain farming activities, our cadres will be required to improve their work methods. However, in the implementation of the party's various rural programs and policies, and in the fulfillment of various tasks, reliance will still have to be placed on rural grassroots organizations including the party organization, the political structure, economic units, and mass organizations, and this is unshakeable. Rural communes and brigades must assiduously take up the economic and political functions for which they should be responsible, actively protect and bring into play the paramount position of the collective economy, and intensify collective unified leadership, control, and cooperation. For example, in the current process of summarizing and improving systems of responsibility for production, collective ownership of the land must be maintained, and earnest attention given protection of cultivated land and rational use of cultivated land. Use of collectively owned cultivated land, garden plots, forestlands, grasslands, water surfaces, and beaches, as well as of barren mountains and wastelands must be put under unified collective planning and arrangements, and no unit or individual is allowed to take private ownership of them. It is strictly prohibited to build houses, make graves, or remove the soil from land that has been contracted for production; commune members may not buy or sell land for which they have contracted production, nor are they allowed to rent it out, to transfer it, or to let it lie uncultivated. All rural grassroots organizations and the broad masses of cadres must take up the cudgels on behalf of these fundamental policies of the party.

In places practicing systems of responsibility linking output to contracting, including places practicing the fixing of output quotas on a household basis or assigning sole responsibility for work on a household basis, in their capacity as organizations in the collective economy, production brigades and production teams must continue to retain their needed economic functions. These include responsibility for equitable distribution and allocation of land contracted for, good management and use of cultivated land; providing of production plans to the collective, to contracting households, and to specialized households; doing a good job in the capital construction of agriculture and in promotion of new agricultural techniques; concluding economic agreements and putting them into effect, fulfillment of quota procurement tasks and collective withholdings; care for the families of martyrs and military personnel; and providing for production by and the livelihood of hardship households. Acting in their capacity as grassroots political units, communes and brigades must do a good job in social rescue work, culture, education, and health work, planned births, militia training, maintenance of public order, and arbitration of civil altercations in order to protect the socialist economy, and guarantee that national laws and ordinances are carried out.

In some rural communes and production brigades where systems of responsibility for production have been rather well perfected, systems of personal cadre responsibility have now been established. Places having the conditions should do likewise. This is advantageous in promoting arousal of revolutionary spirit on the part of rural grassroots cadres, in increasing a sense of work responsibility, in transforming work style, and solving problems in a down to earth way.

PRC EXPANDS IMPORTS, EXPORTS OF BREEDING STOCK

OW161234 Beijing XINHUA in English 1215 GMT 16 Apr 82

[Text] Beijing, April 16 (XINHUA)--China has established trade relations for breeding stock and poultry with more than 30 countries, according to the China National Breeding Stock Import and Export Corporation.

In 1981, China exported for the first time to France and Hungary fine "meishan" breeding pigs indigenous to Jiangsu Province. The sows may have more than 15 piglets at one farrow.

China's varieties of fine strains of livestock and poultry include pigs, cattle, sheep, goats, chickens, ducks and geese, said an official of the corporation. Companies from Japan, Europe and America are now holding talks with the corporation on importing of China's fine strains of breeding stock and poultry, he said.

Last year, he said, China imported more livestock and poultry of fine strains. Included were layers from Britain and Canada, turkeys and queen bees from the United States, meat-type pigs from Hungary, a dual-purpose breed of milk and beef cattle from Austria and Lincoln longwool sheep from Britain.

The imports were aimed at meeting the growing needs of the country's animal husbandry, according to the official. The imported breeding stock and poultry are used to breed fine strains or for hybridization. The 18-month-old hybrid beef cattle, which were hybridized from Chinese farm cattle with a dozen imported strains of beef cattle and the milk and beef cattle, produce about 100 percent more beef than local cattle.

Livestock and poultry breeding in China has grown rapidly since 1979 following the implementation of the new policy of encouraging herdsmen and peasant families to raise animals along with running state stock farms and raising animals by the collective.

BRIEFS

STATISTICAL TRENDS IN SYSTEMS OF RESPONSIBILITY--As of October 1981, 97.8 percent of the 6.01 million basic accounting units in China's rural communes had established various forms of a system of responsibility. Of this total, 81.3 percent had instituted a system of responsibility linked to output, and 16.5 percent had established a system of responsibility of contracting for fixed work quotas. Among those practicing a system of responsibility linked to production, 5.9 percent used specialized contracting with calculation of remuneration being linked to output; 10.8 percent practiced the linking of output to teams; 15.8 percent practiced the linking of output to individual members of the workforce; 3.7 percent practiced partial contracting with individual households, and 38.0 percent practiced contracting of work tasks to individual households. Changes that have taken place in systems of responsibility for production during the past 2 years were as follows. Systems of responsibility of contracting fixed work quotas have given way to a system of responsibility linked to output. Within system of responsibility linked to output, linking of output to teams has given way to linking of output to individual workers, and to fixing output quotas or contracting work tasks to households. Fixing output quotas on a household basis has rapidly declined from the high point of June 1981, changing to the contracting of work tasks to individual households. Contracting of work tasks to individual households has continued to develop. While continuing to develop, output linked to individual workers has begun to divide into specialized contracting and contracting production, and to contracting work tasks to individual households. Specialized contracting has steadily increased, but not a great amount of this is likely to be done over the near term. Currently, production in the system of responsibility linked to output has gradually developed toward grassroots cadres and extension of scientific techniques. [Text] [Beijing ZHONGGUO NONGMIN BAO in Chinese 11 Feb 82 p 3] 9432

MINERAL WOOL PRODUCTION--Beijing, 21 Apr (XINHUA)--China's first mineral wool production line, with an annual capacity of 200,000 cubic meters, imported from Sweden, opened recently at Beijing's new building materials factory. The line produces mineral wool boards, light boards, joint plates and insulation strips, and will meet the nation's basic demand for mineral wool products. The petroleum, chemical, power and shipbuilding industries have all filed orders. Beijing's Changcheng cotton textile mill has experimented with mineral wool to alleviate noise pollution and succeeded in reducing noise inside the mill 9.5 decibels and outside 15.5 decibels. Mineral wool has also been used for sound proofing and heat insulation in factories and high-quality residential housing. [Beijing XINHUA in English 0736 GMT 21 Apr 82 OW]

FRESH EGG PROCUREMENT--Beijing 13 Apr (XINHUA)--The China Foodstuffs Corporation on 13 April reported that fresh egg procurement in China in the first quarter of this year totaled 303.76 million jin, or 58 million jin more than the same period of 1981. With the rapid development in raising domestic fowls the past 2 years, a total of 894 million head of domestic fowls were being raised throughout the country as of early this year. To insure ample supply of eggs to city dwellers, the commercial departments in various localities have signed production and marketing contracts with production teams and chicken-raising families since the end of 1981. Following the implementation of assigned purchases of fresh eggs, both Sichuan and Anhui Provinces have increased procurement in the first quarter to 23.58 million and 24.34 million jin respectively. [OW191431 Beijing XINHUA Domestic Service in Chinese 0754 GMT 13 Apr 82 OW]

LOAN AMORTIZATION RATE UP--During 1981 China's rural financial institutions issued a large number of agricultural loans and had a high recovery rate, winning extremely fine economic benefits. Preliminary statistics from the Chinese Bank of Agriculture show that the Bank of Agriculture and credit cooperatives issued 30 billion yuan in loans and recovered 27.2 million yuan in loans for a 91 percent recovery rate, creating an all-time high. [Text] [Beijing RENMIN RIBAO in Chinese 19 Jan 82 p 1] 9432

SIDELINE PROCUREMENT OVERFULFILLED--1981 was China's best year during the last several for procurement of agricultural and sideline products. Statistics from the National Supply and Marketing Administration show a gross output value of 23.45 billion yuan for agriculture and sideline products procured nationally. This overfulfilled plan for the year and represented a seven percent increase over 1980. The provinces and autonomous regions of Guizhou, Yunnan, Xinjiang, Liaoning, Jiangsu, Shandong, and Jilin had fairly substantial increases, the rate of increase ranging from 10 to 34 percent. ZHOU ZIJIAN AT FOOD INDUSTRY MEETING

OW172118 Hefei Anhui Provincial Service in Mandarin 1100 GMT 16 Apr 82

[Excerpts] The provincial work conference on the food industry held by the Anhui Provincial People's Government concluded on 15 April after a 6-day session. The conference centered on studying the policies and measures for expediting the development of the food industry in Anhui Province in order to better serve the people's livelihood and economic construction.

Zhou Zijian, acting first secretary of the provincial CCP Committee and provincial governor; Su Yu, secretary of the provincial CCP Committee and provincial vice governor; and Huang Yu, provincial vice governor, attended and addressed the conference. In their speeches, they pointed out that Anhui Province still has a great potential for developing its food industry because of its abundant raw materials and a rich tradition in food processing. Because of these superior conditions, the various localities must, in the light of local conditions and taking advantage of the locally available materials, develop high grade, nutritious foods and foods for export in addition to producing popular foods and reviving traditional foods.

Hu Tan, provincial vice governor and chairman of the Provincial Food Industry Association, presided over the conference and made a speech entitled: "Vigorously Develop Anhui Province's Food Industry in Order to Better Serve the People's Livelihood and Economic Construction."

The conference held: Anhui Province has made rapid progress in the food industry over the past few years. The province's total food industry output value reached 2.87 billion yuan in 1981, or 12.5 percent more than 1980. It is projected that the province should increase its total output value to 3.3 billion yuan this year, or 13.8 percent over 1981.

BRIEFS

PROVINCE FINANCES FARM PRODUCTION--The Anhui Provincial Finance Bureau recently held a meeting in Hefei on the task of providing financial support to agricultural work throughout the province. In the past 2 years, the province allocated 463.98 million yuan to support agricultural production despite its own difficult financial condition. These funds were used mainly to support the diversified economy and enterprises in the countryside. The results of utilization of these funds markedly improved after the funds were given in the form of interest-free loans instead of gratis grants. The meeting held that these funds from now on will be channeled directly to communes and their subdivisions to support mainly the diversified economy, reclamation of mountainous areas, household sideline production and poverty-stricken communes, production brigades and teams with due attention paid to economic results. NEED TO HELP NATIONAL MINORITY PEOPLES MARKET PRODUCTS STRESSED

Beijing ZHONGGUO CAIMAO BAO in Chinese 16 Feb 82 p 3

[Article by Kuang Haolin [0400 3185 2651]: "Supply and Marketing Units Should Support Minority Nationality Areas in Economic Development"]

[Text] Implementation of systems of responsibility for agricultural production has brought about a series of changes in the rural economic life of the country. How to adapt to these changes in carrying out work has become a new problem encountered by supply and marketing units in a new situation. When newspapers and periodicals explore this problem, much discussion is devoted to how to satisfy needs for means of production and certain high quality commodities on the part of areas in which the economic situation has taken a turn for the better and by "outstanding" peasants, while little consideration is given to how to support economically backward areas and peasants who are still in fairly straitened circumstances to develop production and raise their standards of living. The situation has been even more so in the case of national minority areas. Historical experiences in this regard very much merit summary and study.

Helping communes and brigades accurately handle the relationship between the "uniform" and "contracting" to assure fulfillment of procurement plans handed down by higher authority is a problem that supply and marketing units in national minority areas must first solve in new circumstances. Decentralized contracting or parceling to commune members for their handling of matters that should have been uniformly administered has caused losses for collective property and has hurt supply and marketing units' fulfillment of procurement quotas. Supply and marketing units in the Xinhuang Tong Nationality Autonomous County in Hunan Province have focused on this situation, using loans to make investments in horticultural farms in some communes and brigades so that they will continue to develop, the communes and brigades assuring repayment of loans from earnings and selling a certain proportion of products to supply and marketing cooperatives. This methods has both consolidated the collective economy and provided reliable assurance of fulfillment of supply and marketing units' procurement plans.

Intensification of procurement and helping communes, brigades, and the masses develop sources of wealth are major ways in which supply and marketing units can support the economic development of minority nationality areas under new circumstances. Most minority nationality areas are relatively poverty stricken, and some places not only lack necessary funds to expand reproduction, but sometimes find it difficult even to sustain simple reproduction, producing a vicious cycle in the economy. At the same time, however, national minority area resources are relatively abundant, and many resources hav yet to be effectively used. If supply and marketing units were able to organize forces for the procurement and processing of certain goods among them and transport them for sale, these idle resources would immediately turn into a "tree that showers money." One example is Chinese yang-ao [Actinidia chinensis], which grows wild throughout national minority areas of western Hunan Province, a large part of which formerly rotted in the mountains because supply and marketing units did not purchase it. During the past few years, Chengbu Miao Nationality Autonomous County and Tongdao Tong Nationality Autonoumous County operated processing industries in conjunction with supply and marketing units. They processed some of the yangtao for canning and for the making of yangtao liquor, which they supplied through the country and marketed outside the country, thereby beginning to make use of this resource and increasing peasant earnings. If a substantial number of the abundant resources in national minority areas could be used in this way, the situation in those economically backward areas could be gradually transformed, and the impoverished peasants could also become prosperous.

Providing the peasants with timely market information and making sure that circulation channels are kept open are other tasks that supply and marketing units in national minority areas must regularly do well under new circumstances. With the implementation of a system of responsibility for agricultural production, particularly the system of responsibility of "large scale assignment of responsibilities," the commodity portion of agricultural products has steadily increased, and peasant dependence on markets has become increasingly great. This requires that supply and marketing units regularly provide peasants market news, in order to have various economic methods guide their production, and in order to avoid blindness in production. In 1980, Xiaoshajiang in Longhui County, Hunan Province, an area inhabited by Yao nationality, produced an excess of the medicinal material, hyssop [Achyranthes bidentata], which supply and marketing units were unable to purchase. As a result they had to burn more than 2,000 dan for a loss of 110,000 yuan, had it been possible to point out the market supply and demand situation to the peasants in advance, such a loss could have been avoided. Now, in minority nationality areas, some supply and marekting units use the signing of contracts as a method for guiding peasant production of staple agricultural sideline products and for the purpose of assuring fulfillment of procurement quotas. Such a way of doing things merits promotion. In order to assure no hitches in agricultural commodities, supply and marketing units are also required to keep circulation channels open. Peasants in the Tongdao Tong Nationality Autonomous County customarily grow ginger, which they have increased in recent years. In 1980, inasmuch as the province's markets were already glutted with ginger and since markets had not been promptly opened in giver-short regions of North China, 1981 ginger production was adversely affected and supply was unable to meet demand.

Additionally, in order to meet the dispersed character of peasant operations following institution of systems of responsibility for agricultural production, and particularly following institution of the system of responsibility of "large scale assignment of responsibilities," supply and marketing units must make commensurate changes in their work. For example, chemical fertilizers and pesticides will have to be sold by the jin and part of a jin; there can be none of the past sales simply by the bag. In the procurement of agricultural sideline products, it will also be necessary to accept them and pay for them whenever they arrive, rather than accept them only in groups. If payment for quota procurement and over-quota procurement of grain in minority nationality areas is made, as in the past, to production teams, fulfillment of procurement tasks will be impaired.

The main problems existing in the livelihood of the people of minority nationality areas are as follows: Certain commodities that the nationalities particularly require cannot be supplied with any certainty. An example is the coarse cotton cloth with white cotton thread cross-stitching needed by Yao nationality women to make skirts. Such a simple commodity cannot be bought regularly in some places. Unless this problem is properly resolved, not only will the masses feel inconvenienced with resultant consequences for development of enthusiasm for production, but it can develop into a nationality problem. It should evoke careful attention on the part of supply and marketing units. In the wake of institution of systems of responsibility for agricultural production a small number of fairly prosperous peasants have also shown up in minority nationality areas. They also urgently want to buy bicycles, sewing machines, and such high grade commodities. However, some areas cut back on shipments to minority nationality areas of such commodities, or they substitute run-of-the-mill goods for name-brand goods. This requires correction.

CONTRACTS BETWEEN PEASANTS AND COMMERCIAL UNITS PUSHED

Beijing ZHONGGUO CAIMAO BAO in Chinese 16 Feb 82

[Article by Commentator: "Let Peasants Know a Year in Advance"]

[Text] The situation survey of the agriculture and commerce contract system promoted by Dazhu County that this newspaper has published today very much deserves to be read by comrades everywhere who are engaged in rural commercial work.

The agricultural economy is an important integral part of the national economy and it must adhere to taking a planned economy as the key link, making regulation by the marketplace supplementary. Promotion of a system of agricultural and commercial contracts whereby agricultural and commercial contracts dovetail colleetive and individual commune member production activities with state plans constitutes a fine method for combining state plan guidance with respect for peasant self-determination.

Agricultural sideline products are of numerous kinds, and the quantity of social need for each kind of product is restricted by diverse elements. Which products require development, and which ones require control of quantities or improvement of quality all pose problems in individual planning arrangements. Unless plan guidance is instituted blind production with an imbalance between supply and demand may result to the deteriment of the welfare of the peasants, the collective, and the state. Promotion of a system of agricultural-commercial contracts can let the peasants "know a year in advance," and relieve peasant apprehensions about being taken unawares about outlets for their products. At the same time such contracts would help assure implementation of state production plans for agriculture as well as fulfillment of agricultural sideline product procurement in stipulated quantity and quality, would help support the position of major channels for the circulation of commodities, and would prevent various kinds of illegal assaults on major channels. In short, agricultural-commercial agreements have numerous advantages and should be actively promoted step by step.

Looked at in terms of the country as a whole today, promotion of a system of agricultural-commercial agreements is not yet sufficiently widespread. Though some places have promoted agricultural-commercial contracts systems, the honoring of such contracts is insufficiently ideal or even merely a formality. What is the reason? There are problems in organizational leadership, but more important is problems of ideological perception. One fairly universal perception is that the signing of agricultural-commercial contracts is regarded only as one method for fulfilling agricultural sideline products procurement quotas; consequently, in the course of promotion there are no discussions on a basis of equality but rather reliance is placed on administrative commands. Naturally this is not welcomed by the peasants. Signing of contracts is a two-sided matter, and there can be no desire merely on the part of one party. Both parties to a contract should enjoy the rights to which they are entitled and bear the responsibilities they should bear with no advantage solely for one party. Following the experiences of Dazhu County, before the signing of contracts, the role of agricultural-commercial contracts should be widely propagandized among the peasants and indoctrination in "simultaneous concern for three" should be carried out. In the process of concluding contracts, repeated discussions should be held with peasants in an effort to formulate equitable base figures that satisfy both parties. Commercial departments must also bear responsibility for providing technical guidance and means of production. Agricultural production is prone to the effects of natural disasters and contains an element of uncertainty. Should it happen that human efforts cannot prevail against natural disasters, initiative should be taken to discuss revision or cancellation of contracts with the peasants. These were important elements in the universal spread and honoring of the agricultural-commercial contracts system in Dazhu County.

In promoting an agricultural-commercial contract system, a conscientious job should be done in authenticating, checking, and arbitrating contracts, to firmly uphold the solemnity of contracts. The state designates industrial and commercial administration and management units as authenticating organs for economic contracts, and only following authentication do agricultural--commercial contracts possess legal validity. In the process of formulating agreements between agriculture and commerce, industrial and commercial administration and management units should not only understand provisions for examing contracts so that contracts are in accordance with policy requirements, but they should also understand circumstances under which contracts may be checked to discover problems and handled impartially. In order to maintain the solemnity of contracts, industrial and commercial administrative and management units are to institute arbitrarion when contracts are not carried out. The impetus behind the agricultural-commercial system in Dazhu County was very much related to that industrial and commercial administrative and management units brought into play the role of authentication, checking, and arbitrarion.

A whole year's plans are decided in the spring, and now the broad masses of peasants and commune and brigade cadres are in process of figuring out how much of what crops they will plant and arranging plans for a year of agricultural production. Rural commercial units everywhere should not miss the opportunity to take the initiative in propagandizing implementation of an agricultural-commercial contract system letting the peasants know a year in advance and making a new contribution to winning a bumper harvest in agriculture this year.

ACCOUNTING METHODS READJUSTED TO OUTPUT QUOTAS

Beijing GONGSHE CAIWU in Chinese No 2, 6 Feb 82 pp 22-24

[Article by Economic Management Section, Xiaogan Prefecture CCP Committee Office: "Investigation of Several Problems in Production Team Financial Accounting Work Following Assignment of Output Quotas to Individual Laborers"]

> [Text] Editor's Note: Accompanying promotion of rural systems of responsibility for production has been the rise of new circumstances and new problems in financial accounting work. How accounting work should adapt to new demands following institution of system of responsibility is an important link in current perfection of various systems of responsibility. A look at investigative data from the Xiaogan Prefecture CCP Committee Office as to how to improve and simplify bookkeeping and account reckoning methods for a system of responsibility that links output to individual laborers is a major measure in implementation of these systems of responsibility, which are printed here for the study and reference of all.

Following the linking of output to individual laborers, what new circumstances and new problems appeared in the financial accounting work of production teams, and how should they be solved? With these problems in mind, we recently conducted an investigation at Tuanshan Production Brigade in Pengdian Commune, and at Fengdian Production Brigade in Fengdian Commune, Dawu County. In 1981, eight production teams in these two production brigades instituted collectively managed linking of production to individual laborers. Following the linking of production to individual laborers, except for production plans, management and use of water sources, farmland capital construction, and combat against calamities, all of which bear on the principal farming activities of the entire brigades and were handled by the brigades, most production activities were conducted by the contracting commune members themselves. Following changes in forms of administration, financial accounting work also had to undergo commensurate improvements. For the past year they have explored and accumulated some experiences. Now, as part of year end distributions, further reflection and summarization has been done on financial accounting work during the past year, and the following four reforms effected.

1. Change of Uniform Receipts and Uniform Expenditures To Contracting Sole Responsibility for Receipts and Expenditures

Before the advent of systems of responsibility linking production to individual laborers, the various production management activities were handled by using financial methods of uniform receipts and uniform expenditures. Following the linking of production to individual laborers, contracts linking production were formulated on the basis of fixing output quotas (earnings), fixed work quotas, and sole responsibility for costs. The fixing of output quotas (earnings), and fixed work quotas are, in fact, a fixing of sole responsibility for earnings and expenditures. However, at the outset, there was no understanding on this issue. When advance distributions were made against summer earnings, they were still made on the basis of uniform receipts and uniform expenditures. Earnings were tendered to production steams and expenses were assigned downward; distributions were made only after grain was stored. There were numerous problems in doing things this way, first of which was that the complexity of procedures increased the numerous unnecessary difficulties, resulting in a waste of manpower and material resources. Secondly, some of the grain turned over to families and households was dry and some damp; some was plump and some was not, making for difficulties. Some commune members feared that if they turned over good grain, they might be issued bad grain, so they did not want to turn their grain over to the production team. Furthermore, when households sold grain in excess of quotas, production teams issued affidavits, and when individual commune members sold grain in excess of output, they could get no cash, which hurt their eagerness to sell grain. Consequently, at the time of fall distribution of earnings, excess public grain and agricultural taxes were apportioned among households on the basis of area contracted for, the households selling the grain and settling their own accounts, and consumption grain for commune members being no longer turned over to production teams. Only in this way could the above mentioned conflicts be resolved. However, in the fixing of output quotas, the fixing of work quotas, the fixing of responsibility for costs, and the fixing of public grain quotas, fixing was done only for commune members and not for collectives. Therefore, for expenditures made by the collectives, that meant withdrawal of whatever was to be spent, reimbursement being made for whatever was spent. But there were a large number of loopholes. Take the case of No 6 Production Team in Tuanshan Production Brigade where production expenses greatly declined last year as a result of the fixing of sole responsibility for costs on individual households, falling from 32 percent of gross income during the previous year to 15 percent. However, great waste continued to exist in expenditures for management, more than 110 yuan having been spent as expenses for eating, drinking, and entertainment alone, and cadre subsidies increased an average 12 yuan per person. Because of mass demand, fixing of sole responsibility was also instituted for expenditures by the collective, and one after another the eight production teams changed from the former system of uniform receipts and uniform expenditures. The actual way in which this was done was to fix output quotas (income) and to fix responsibility for costs, using this basis for sharing among households of excess public grain and agricultural taxes according to the area contracted for, to fulfill sole responsibility. Public accumulation fund, public welfare fund, and management expense withholding tasks were done on a household basis, households assuming sole responsibility for tendering them to higher authority. Commune members withheld production expenses for their own use, balancing revenues against expenditures. The portion for distribution to commune members was not turned over to production teams but withheld by commune members in lieu of distribution. Cadre subsidies and office expenses were the sole responsibility of commune members, but if agreed upon amounts were exceeded, commune members bore no further responsibility for payment. At the beginning of each year firm agreements were made, and except for the occurrence of some particularly severe disaster, these agreements were not readjusted. Once responsibility for financial receipts and expenditures were assigned to commune members, production teams no longer did any direct accounting. In this way, financial procedures were greatly simplified. The 12 production teams in Fengdian Production Brigade settled accounts once, the annual assigned output of grain for this brigade being somewhat more than 85,000 jin and cash earnings amounting to somewhat more than 5,000 yuan. After institution of sole responsibility for receipts and expenditures, a lot of dealings back and forth were eliminated and more than 800 fewer entries were made in ledgers. Thus, not only were procedures simplified, and more importantly loopholes in financial work increased, but the method also helped the program of democratic commune operation and operation of communes on a basis of hard work and frugality.

2. Change From Formulation of Plans on the Basis of Actual Output to Formulation of Plans on the Basis of Fixed Output Quotas for Earnings Distributions

Following the linking of output to laborers, on what output (earnings) should plans be formulated for earnings distributions? On actual output or on fixed output quotas? This problem was encountered at the time of advance distribution of summer earnings. At the time of the summer harvest in 1981, we ran a pilot project on earnings advances at Fengdian Production Brigade. At that time some advocated formulation of plans on the basis of fixed output quotas (income), their reasons being that "in linking output to individual laborers, overproduction is rewarded and under production penalized, the responsibility being that of individual commune member households. Formulation of plans on the basis of fixed output quotas (income) and formulation of plans on the basis of actual output are, in fact, the same in their result." Some disagreed with this view saying that "formulation of plans on the basis of fixed output quotas could not reflect the distrbution situation and production results." The result of the controversary was a decision to formulate plans on the basis of actual output. Advances against summer earnings were made on the basis of estimated output with the adoption of a combination of reports from commune members themselves and checks made by production team committees. In using work points as a basis for distributions, those derived from contracted work were figured on the basis of task completion; those obtained from other than contract work were figured on the basis of actual work time. Expenditures were figured according to contract figures. Portions exceeding fixed output were used as commune member bonuses, and portions below fixed output had to be recompensed by production households that had fallen short in delivering quotas, the amount being deducted from distributions to production households in areers.

This investigation revealed that this method was not uniformly followed, the reasons being: 1. Formulation of plans on the basis of actual output meant that transfers of accounts had to be made for amounts over and under quotas, and false income and false expenditures had to be entered into distribution plans and ledgers. Transfer of accounts was complex. Accountants found it hard to learn, and the masses could not make heads or tails of it. 2. Outputs (earnings) could not be readily verified. Some commune members feared showing themselves to be prosperous, feared that bonuses and penalties would not be honored, or feared that next time their output quotas would be fixed at a higher figure, so they were unwilling to report actual outputs. 3. At the present time mass fears of a change in policies have yet to be completely resolved, and house by house inquiries to verify output increased mass apprehensions and impaired the enthusiasm for production of commune members. Therefore, how could formulation of plans on the basis of fixed output quotas reflect the results of a year's production and the distribution situation? Working together with the cadres and commune members of the two production brigades, we studied the following two methods. (1) Statistical accounting. A representative sampling made at year's end to make overall calculations and prepare statistical tables showing production and distributions. (2) Fiscal accounting. In brigades in which the mentality of the masses is good and level of accounting personnel fairly high, a year end house to house registration to be conducted and an entry made in a ledger, the registration table to be used as a voucher for accounting purposes. In the end the eight production teams wanted to use the first method. Everyone said that "this method is easy for accountants to figure and easy for the masses to understand. It is plain and clear, saves a lot of bother and work, and helps consolidate and perfect the system of responsibility linking output to individual laborers."

3. Change from Distributions First and Accounting Later to Beginning of the Year Stringent Formulation of Quarterly Reconciliations

Formerly when the production teams used uniform income and uniform expenditures, distributions were made at year end on the basis of actual output (earnings), actual expenditures, and actual labor used. This determined a system whereby advance distributions were made in summer and fall, and a final accounting made at the end of the year. Following the linking of output to individual laborers, fixing of output quotas, fixing of work quotas, fixing of responsibility for costs, and sole responsibility for receipts and expenditures, plans were formulated on the basis of fixed quotas. Under these new circumstances, should the old method of "distribution first and calculations later" continue to be used? On the basis of a year's experience, and following analysis and summary, it has been decided that beginning in 1982 a system will be implemented for "beginning of the year formulation of plans with quarterly reconciliations". The specific method to be used is as follows. In accordance with the various systems of responsibility linked to output signed by production teams and commune members, and on the basis of pertinent data about fixed output quotas (earings), fixed work quotas, and fixed responsibility for costs, and in accordance with the principle of "concern for the interests of the three" [communes, the collective, and individuals], plans are to be formulated for the entire year about materials (grain, cotton, and oil-bearing crops) and cash distributions. On the basis of the situation for outputs (earnings) contracted by individual households as well as for the "three things retained" (grain rations, seeds, and livestock feed), state procurement quotas, agricultural taxes, and collective withholdings (public accumulation funds, public welfare funds, and management expense) are to be shared by individual households, each household itself witholding seed and production expenses. After procurement quotas, production team withholdings, seeds and livestock feed have been deducted from commune member grain production, the remainder is their own grain ration for consumption. After agricultural taxes, production team withholdings, and production expenses have been deducted from commune member earnings resulting from contracting, the remainder is distributed income. This way of doing things has many advantages. First, it truly achieves "notice a year in advance." Once distribution plans have been formulated at the beginning of the year, both the collective and individual commune members have a basis to work from, and every household can formulate its own plans on the basis of the production team plan. Second, it simplifies distribution procedures. There is no need to formulate further advance distribution plans in summer and fall, but rather simply to perform an economic check up and settle contracts. So long as standards for fixing output quotas remain unchanged, distribution plans require no further changes. Third, at the year end final accounting, there is no further wrangling among commune members as to who got what and who did not get what grain rations. Grain rations for individual hardship households are included in contracts at the beginning of the year and are provided for from collectively withheld grain.

4. Change of Workpoints Gained From Non-Contracted Work to Assignments to be Undertaken, Shortfalls to be Made Up by Individual Households

Institution of systems of responsibility linked to output, all renumeration to be calculated on final labor results, solved egalitarianism in the computation of renumeration of labor. However, workpoints earned from other than contracting, as from capital construction of farmlands or from odd jobs, for instance, were still workpoints figured on time worked. Since work efficiency was generally low, to use them in the same way as fixed work quotas in making distributions was inequitable. In order to solve this problem, in addition to exercising strict control over non-fixed quota work and doing everything possible to expand fixed quota contracting of work, reforms were also made in methods of settling accounts as follows: (1) Cadre allowances were changed from supplemental work points to supplemental money. Workpoints owing as allowances were converted into cash on the basis of average workpoint value, and a firm agreement made at the beginning of the year. Eighty percent was treated as a fixed allowance and 20 percent depended on the the outcome of year-end discussion and appraisal of work performance. (2) Allowances for capital construction of farmlands and for doing odd jobs were shared, on the basis of the area contracted, among individual households who had responsibility for paying them by mutually making up shortfalls, no sharing in distributions permitted.

NEW EMPHASIS GIVEN RURAL COST ACCOUNTING

Beijing GONGSHE CAIMAO in Chinese No 2 1982 p 42

[Article by Xi Shuren [5977 2885 0088]: "Ministry of Agriculture Convenes Symposium for Farm Products Cost Accounting Points"]

[Text] In November 1981, the Ministry of Agriculture convened a National Symposium for Farm Products Cost Accounting Points at Xiangtan in Hunan Province. Special cadres in charge of this work in each province, municipality, and autonomous region, some operating point cadres, teachers from institutions concerned and research workers summarized and exchanged operating point work experiences at the conference, and studied problems in how to do a further good job of farm products cost accounting in a situation in which rural villages have instituted various forms of production responsibility systems.

In the 2 years since the beginning of agricultural cost accounting, a great amount of work has been done under the leadership of all levels of government, and as a result of active efforts made by grassroots cadres, commune members, and operating point cadres. Throughout the country, with the exception of Tibet (Taiwan not counted), 275 points are in operation. In addition, localities are operating another 1,237 points. According to incomplete statistics, 179 cadres have been relieved of other duties in preparation to operate points, and 4,739 people at various pilot point communes and brigades have had an elementary education in agricultural product cost accounting work. Some production teams having a large proportion of fruit trees, fisheries, tea, silkworm mulberry, and flue-cured tobacco have begun to list these items in their accounts. In the suburbs of Beijing, Tianjin, and Shanghai vegetable cost accounting has been instituted, and in the pastoral areas of Nei Monggol, livestock product cost accounting pilot projects have begun to operate. In addition, a survey of living expenses needed by workforces for reproduction, and a collation of 1980 agricultural products cost accounting data are underway to provide important figures on commune member earnings and expenditures, and on costs of producing farm corps. This has received serious attention from leaders at all levels, and has been welcomed by research units concerned. On the basis of actual expenditures for labor and materials, some points have established blueprints for labor quotas and expenditure quotas. Some places have used this as a basis for signing contracts with commune members that fix work quotas, fix output quotas, or fix investment to promote perfection and uplifting of production responsibility systems.

Comrades attending the conference used a large body of acts to show that practice of agricultural product cost accounting play an active role in formulation of equitable quotas, tapping labor potential, conservation in all kinds of expenses, equitably arranging planting plans, improving administration and management, promoting the extension of science and technology, and in bringing about increased output and increased earnings. Budgetary estimates from 183 pilot point units in 24 provinces, municipalities and regions shows the following comparisons between 1981 and 1980: Agricultural earnings increased 10.6 percent; expenditures for agricultural production expenses decreased 4.8 percent; collective accumulations increased 14.10 percent; commune member distributions increased 12 percent; and average per capita earnings increased by 17.50 yuan. For every 100 yuan invested for production expenses (materials), agricultural earnings rose from 276 yuan in 1980 to 321 yuan in 1981, an increase of 16.3 percent. Gross earnings derived from the investment of each workday rose from 1.59 yuan in 1980 to 1.79 yuan in 1981, an increase of 12.6 percent. Numerous facts show that no matter whether in South China or North China, or in bumper years or lean years, and no matter the system of responsibility practiced, given the same conditions, greater economic results come from units with cost accounting as compared with units without cost accounting.

The conference emphasized briefings on how agricultural product cost accounting was carried out following institution of various forms of responsibility systems. Many comrades used vivid facts to demonstrate that both cost accounting and production responsibility systems are both important integral parts of administration and management. Implementation of cost accounting on a foundation of various kinds of production responsibility systems can more accurately and more concretely measure economic results, thereby promoting the perfection of production responsibility systems. Perfection of production responsibility systems creates, in turn, conditions for strengthening cost accounting, enhancing cost control, and reducing product costs. Consequently, even though most cost data in some production teams has to be obtained from individual households, continued good work of agricultural cost accounting in these production teams is also very significant. Everyone acknowledged that the basic theories, basic principles, and basic methods contained in National Agricultural Commission 1979 document number (62) pertaining to the stipulation and formulation of "Plans" are still applicable. However, as a result of the development of diverse forms of production responsibility systems, collection and collation of data and certain accounting methods require corresponding changes.

The symposium also studied and took action on the strengthening of leadership of this work, on suitable increases in some pilot project units, on doing a good job of training and the compilation and analysis of cost data, and on survey of living expenses required by workforces for reproduction.

DONGSHAN COUNTY SPRING GRAIN--A bumper harvest of spring grain has been reported from Dongshan County, Fujian Province. The total output shows a 20 percent increase over last year, while the average per-mu yield is 39 jin more than last year's figure. As of 16 April, the county had fulfilled 25 percent of this year's spring grain procurement quota. [OW281257 Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 24 Apr 82]

BRIEFS

PROVINCIAL AFFORESTATION--According to the Provincial Afforestation Commission, Gansu Province had afforested 230,000 mu of lands, up 46.4 percent, grown 20,000 mu of saplings, up 184.0 percent, and planted 14 million trees by the sides of highways and farmlands and around lakes and houses, up 18.7 percent compared to the corresponding 1981 period. Over 14 million trees had been voluntarily planted by the people. [SK150150 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 13 Apr 82]

HOG PRODUCTION POLICY--The Gansu Provincial People's Government recently issued a circular urging government organs at all levels to strengthen leadership over hog production and stabilize various policies on hog production. The circular emphasizes: It is not permitted to arbitrarily change policies on hog procurement, prices, awards sales and collective fodder distribution adopted by the state and the province. The state's purchasing departments should sign contracts with production brigades assigning production quotas to them and promising them a purchase. [SK180958 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 16 Apr 82]

SUGARBEET PLANTING--Wuwei, Zhangye and Jiuquan prefectures have planted 85,000 mu of sugarbeets in accordance with the state plan, 10,000 mu more than planted in 1981. [SK180952 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 16 Apr 82]

PROVINCE HIT BY EARTHQUAKE--According to our sources, based on the determination of the provincial seismic network, at 1436 on 14 April an earthquake measuring 5.7 on the Richter scale hit places east of Zhenyuan County and where Gansu and Ningxia Provinces meet. According to preliminary estimates, the magnitude of the seismic disturbance in Zhenyuan County's (Fuxin) commune was stronger than in other places and part of walls there were cracked and damaged slightly. No injuries and deaths have been reported. The details are under investigation. After the earthquake, the Provincial Seismic Bureau immediately held an emergency meeting. The meeting decided to send professional personnel to conduct on-the-spot investigations. Discussions at the meeting pointed out that there will be no disruptive earthquake in Zhenyuan County in the near future. [Text] [SK160703 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 15 Apr 82]

VEGETABLE PRICES--The Lanzhou Municipal Pricing Committee in Gansu Province recently decided to set ceiling prices on several vegetables sold at farm produce markets. Twenty-two vegetables including chives, spinach, cucumbers, and eggplant have their prices limited. The prices of these vegetables are not allowed to be sold at prices 50 percent higher than the state retail list prices. [SK142207 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 13 Apr 82]

BRIEFS

METEOROLOGICAL WORK CONFERENCE--The Guangdong provincial meteorological work conference and the provincial meeting of progressives in meteorological work were held in Guangzhou from 1 to 8 April. The conference looked into this year's work. The conference selected 23 advanced collectives and 34 advanced workers in meteorological work. In addition, the Provincial Meteorological Bureau commended and awarded prizes to 10 advanced meteorological posts, including Bingcun commune meteorological post in Mei County. The conference demanded that meteorological departments at all levels seriously do well in capital construction of the meteorological forces, training work and improving the technical and professional levels of the meteorological forces. [Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 8 Apr 82]

SPRING FARMING--According to the statistics, by 12 March Guangdong Province had sown some 283 million jin of early-rice seeds, fulfilling 56 percent of the quota. Shantou Prefecture and Zhuhai Municipality had completed their spring sowing quotas. Foshan Prefecture and Shenzhen Municipality had sown some 70 percent of their quota of early-rice seeds. Hainan Island, whose season comes relatively early, had transplanted early rice on 2.13 million mu, 81 percent of the planned early-rice fields. All localities throughout the province had cultivated more and better spring-sown crops than in the corresponding period of last year. [HK241219 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 22 Mar 82]

CHEMICAL FERTILIZER PRODUCTION--Guangdong Province produced some 165,000 tons of chemical fertilizers in the first quarter of this year, overfulfilling its quarterly quota by 13.9 percent. Output in the first quarter of this year was 12.5 percent more than in the corresponding period of last year. Three large and medium-size backbone chemical fertilizer enterprises--Guangzhou petrochemical works, Guangzhou nitrogenous fertilizer plant and Zhanjiang chemical works--overfulfilled their quotas for chemical fertilizer production for the first quarter. Production of urea in Guangzhou petrochemical works increased by 41.8 percent. Output of all small chemical fertilizer plants throughout the province was also more than in the corresponding period of last year. The consumption of oil for the production of each ton of synthetic ammonia in Guangzhou petrochemical works dropped by 25 kg. The consumption of sulphuric acid for the production of each ton of phosphatic fertilizer dropped by 117 kg. The consumption of coal for the production of each ton of synthetic ammonia in all small nitrogenous fertilizer plants throughout the province dropped by 62 kg and the consumption of electricity dropped by 77 kilowatt-hours. Due to the increase of production and the reduction of consumption, the chemical fertilizer trade in the whole province made a profit of 3.86 million yuan in January and February this year. [Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 9 Apr 82]

PARTY POLICIES REPORTEDLY PUT POOR COUNTY ON ROAD TO RICHES

Shijiazhuang HEBEI RIBAO in Chinese 29 Jan 82 p 1

[Article by Zheng Tong [6774 1749] and Jin Youxin [7246 2589 2450]: "Considerable Changes Appear in 'High Yield Poor County' Situation of Zhengding County. Promotes Responsibility System, Diversifies Into Cotton, and Develop Economic Diversification"]

[Text] Zhengding County has diligently implemented the line, the programs, and the policies of the Third Plenary Session [of the 11th Party Central Committee] to effect considerable changes in its situation of being a "high yield poor county." In 1981, despite prolonged and serious drought, agricultural output showed tremendous increase over 1978 when the weather was excellent. Grain showed steady development, total cotton output increased 2.4 times; fats and oils increased by 79 percent; netearnings from agriculture increased 49.2 percent; commune member grain rations increased from 458 jin to 530 jin; average per capita income increased 55.6 percent; commune members savings deposits increased 1.2 fold, and peasant purchasing power increased more than sixfold.

Several years ago Zhengding County had been rather seriously affected by "leftism." It practiced single crop agriculture; production was done without calculating costs; unrealistically high output quotas and state procurement quotas were set, and though grain yields were greater than 1,000 jin, commune members had no money in their pockets and no grain in their homes. By 1978, half the peasant households in the county went outside the county to buy high-priced grain, and it became a notorious "high yield poor county." Following the Third Plenary Session, the County CCP Committee and county government summarized the lessons of experience in a realistic way, cleared away "leftist" influences, and diligently put into effect the party's policies, bringing about a upturn throughout the county's rural villages.

First they promoted and put in place agricultural production responsibility systems linking output to calculation of remumeration. Today, 1,820 of the county's 1,999 production teams practice various forms of production responsibility systems. Several years ago labor efficiency was low and costs of producing grain and cotton were high in Sanjiaocun Production Brigade, which has high yields of both grain and cotton. It was renowned throughout the country as a high yield poor county. After grain and cotton output in 1981 increased by 360,000 jin over 1978; cotton output increased 1.1 times; net earnings increased by 545,000 yuan; production expenses fell by 45,000 yuan, and average per capita standards of living rose from 111 yuan to 240 yuan. In the space of 2 short years following institution of responsibility systems, the situation in 216 poor production teams in the county changed.

Second was readjustment of the internal structure of agriculture; vigorous efforts going to development of cotton production with gradual compensations being made in development of grain and economic crops. Formerly, as a result of grain squeezing out cotton, the area sown to cotton fell from 190,000 mu to slightly more than 120,000 mu, and yields dropped from 120 jin per mu in 1971 to 35 jin in 1978. Following the Third Plenary Session, while stabilizing grain output, they took the cottom situation firmly in hand. In 1981, earnings from cotton alone averaged 65 yuan per capita, and tremendous increases also occurred in oil-bearing crops. Average annual per capita consumption of edible oil rose from the former 1.5 jin to more than 6 jin. In numerous communes and brigades grain and cotton also increased.

Third was development of economically diversified production mostly in the form of household sideline industries, which opened a main gate to curing poverty and becoming prosperous. Throughout the county appeared large numbers of "outstanding households," who had become prosperous first. This county has an average 1.4 mu of land per capita. Figuring one member of the workforce to farm 5 mu of land, 47 percent of the workforce is surplus to needs. However, some years ago, this surplus labor was not permitted to engage in industrial sideline production and people were restricted to the limited amount of land where they dawdled in poverty. Now that the County CCP Committee and county government have raised the slogan of "liberate the mentality and dare to become rich," the surplus workforce has shown its mettle, and breeding industries, processing industries, and planting industries have burgeoned. From the Standing Committee of the County CCP Committee to ordinary cadres relieved of production duties, everybody is devoted to "helping enrich households." More than 90 percent of peasants are engaged in diverse household sideline occupations such as raising milk cows, raising goats and sheep, raising rabbits, raising chickens, raising martens, growing flowers, or raising fish.

BRIEFS

DAIRY PRODUCTS--By the end of March, Heilongjiang Province had produced 4,740 tons of dairy products, up 38.5 percent over corresponding 1981 period and an all-time high. According to incomplete statistics, the province's 16 key dairy enterprises had yielded 4.43 million yuan in profits, up 10 times over the corresponding 1981 period. [SK200954 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 19 Apr 82]

PROVINCIAL AFFORESTATION--As of 19 April, Heilongjiang Province had built 300,000 mu of shelter belts and planted 400,000 trees. Heilongjiang Province plans to afforest 3.5 million mu of land and grow 2 billion saplings this year. [SK200950 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 19 Apr 82]

WHEAT PLANTATION--Hejiang Prefecture, Heilongjiang Province, plagued by flooding last year and spring waterlogging this year, has successfully fulfilled its 1982 wheat sowing plant. By 16 April, the prefecture sowed over 2.97 million mu of wheat. [SK190608 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 18 Apr 82]

WHEAT SOWING--By 9 April, Heilongjiang had fulfilled 51 percent of its wheat sowing target by sowing 15.6 million mu, 3.7 million mu more than in the corresponding 1981 period. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 10 Apr 82]

SPRING WHEAT--Harbin, 6 Apr (XINHUA)--Heilongjiang had sown spring wheat on 3 million mu by 1 April, an increase of 1 million mu over the corresponding period last year. [OW071251 Beijing XINHUA Domestic Service in Chinese 0111 GMT 6 Apr 82]

SPRING SOWING--While planting wheat, rural communes and brigades and state farms in Heilongjiang Province have lost no opportunity to plant field crops. As of 15 April, the province had planted field crops and such cash crops as flax and sugarbeets on 1.86 million mu of land, an increase of 625,000 mu over the corresponding 1981 period. [SK190838 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 18 Apr 82]

FARM PRODUCE EXPORT--In 1981 Heilongjiang exported 150,000 tons of soybeans and 43,000 tons of flax, more than 80 percent of the total flax exported by the country. Heilongjiang also exports vegetables, wild plants, medicinal herbs, Chinese medicines and fur products. Every year the province exports about 7,000 tons of vegetables and wild plants. It earns $100 million from exporting medicinal herbs and Chinese medicines and $2.7 million from fur products annually. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 9 Apr 82]

PROVINCE REPAIRS DAMS--Among the 297 river dams damaged by floods last year, 226 dams--or 91 percent--have been repaired, resuming irrigation for 1.55 million mu of farmlands in our province. Of the restoration construction, 30 percent was built with funds raised by the masses. [SK090520 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 8 Apr 82]

COUNTY FIELD CROPS--Having fulfilled the wheat sowing task, Bayan County, Heilongjiang Province, has shifted its attention to sowing field crops in a timely manner. As of 15 April, the county had sowed 114,000 mu of field crops. [SK180900 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 17 Apr 82]

DAIRY-FARM PLANNING--The China National Technical Import Corporation has formally signed a loan contract with the Denmark Dairy Product Equipment Corporation on technical assistance and equipment supply for building the No 2 Heilongjiang provincial dairy product plant at Anda County in the province. Under the contract, the Danish Government offers a 25-year interest-free loan of 15 million yuan. The plant's acreage is 100,000 square meters. The plant's daily production capacity would be 200 tons of fresh milk, and major products include milk powder, nonfat milk powder and butter. The annual output of these products would be 7,000 tons. The plant would be expected to make an annual profit of 11 million yuan. Ground breaking for this plant will be held in the second quarter of this year. Construction work will be completed in 1985. [Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 6 Apr 82]

COUNTY WHEAT SOWING--By 8 April Tangyuan County in Heilongjiang had sown 170,000 mu of wheat, overfulfilling its wheat sowing plan by 14.8 percent. [SK101111 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 9 Apr 82]

CSO: 4007/382

BRIEFS

RURAL INCOME--Hunan reaped an all-round bumper harvest last year despite various natural disasters. The peasants' average distribution income exceeded 100 yuan for the first time. According to statistics, total income of the basic rural accounting units in the province was 7.963 billion yuan, an increase of 451 million yuan over 1980. This represented an average income of 172.9 yuan per head of population taking part in the distribution. [HK100710 Changsha Hunan Provincial Service in Mandarin 2310 GMT 2 Apr 82]

AGRICULTURAL PRODUCT REGULATIONS--To strengthen the planned management of the first and second-category agricultural and sideline products, the Hunan Provincial Government recently formulated regulations on export of agricultural and sideline products from the province. The regulations point out that when the first and second-category agricultural and sideline products are exported from the province, it must be reported to the relevant provincial departments for examination. After the departments agree, they issue export licences. Otherwise, railway, road, civil aviation and shipping departments are not allowed to transport them and banks are not allowed to settle accounts. When an individual carries, asks others to carry or mails staple agricultural and sideline products out of the province, the quantity must be limited: not more than 40 jin of rice, not more than 20 jin of beans, not more than 10 jin of oil, not more than 20 jin of pork, beef, eggs and fresh fish and not more than 5 jin of tea, flue-cured tobacco and day lily. CITRUS PRODUCTION EXPANDS IN TAI HU AREA

Nanjing XINHUA RIBAO in Chinese 21 Jan 82 p 2

[Article: "Jiangsu Citrus Production Last Year Reached 15,500 Tons"]

[Text] For the past several years, some countries and municipalities in Jiangsu along the banks of the Tai Hu have made a certain amount of progress in combatting cold and frost to cultivate citrus. Statistics show that last year the province's total citrus production exceeded 15,500 tons, up over 500 tons from the bumper 1979 crop and a historical record.

The area along the Tai Hu is on the northern edge of the semitropical zone and frequently suffers from frost. Nonetheless the low hilly areas of some regions are relatively suited to the production of citrus due to the regulatory influence of the atmospheric moisture of the lake. Over the past several years, the relevant production, scientific research and educational departments carried out numerous on-the-spot investigations and helped the communes, brigades and teams in the hilly and mountain areas around the Tai Hu to develop citrus production in keeping with local conditions. The suburban areas of Wuxi and Wu county also set up over 70 weather observation sites in their orchards and nurseries in order to select regions which were most suited microclimatically to citrus.

In order to avoid frost damage effectively and ensure that the citrus crop passes safely through the winter, the communes, brigades and teams in the citrus districts have paid attention to selecting varieties which have a relatively strong adaptability. The horticultural office of the provincial institute of agricultural sciences and the fruit tree office of Wu county have worked for 7 years in a row to select 10 fine single plants, including the cold resistant, early ripening Zaohong No 2 and the seedless, early ripening Wenzhou 57-5 mandarin orange. These fine single plants have grown well despite numerous incidents of low temperatures of 8.3-8.7 degrees below zero. The Jiangsu Department of Agriculture and Forestry has allocated funds to set up points in Wu county, Wuxi municipality and Wujin county and for establishing a 30 mou nursery for selecting good graft varieties, in order to supply good scions for propagation.

EDITORIAL URGES STABILIZATION OF GRAIN PRODUCTION

Nanjing XINHUA RIBAO in Chinese 19 Jan 82 p 1

[Editorial: "We Must Pay Close Attention to Grain Production"]

[Text] A strategic task facing the rural cadres and masses throughout the province during the new year is to continue to carry out intact the policy "in no way relax grain production while actively diversifying economically" and pay close attention to grain production, guaranteeing its stable growth while at the same time making full use of various resources to further carry out economic diversification. This is an important material base for further consolidating and developing the political situation of stability and unity and promoting the smooth development of various construction activities.

Grain is the "treasure among treasures." "With grain in hand, you feel quite grand." "When the granaries are full, there's prosperity in all." There is a great deal of truth in these wise remarks of those with experience. For a number of years the livelihood of our province's people has been stable and there has been a rapid development in agriculture, forestry, animal husbandry, sidelines and fishery. A vital factor in this growth has been our maintaining a certain level of growth in grain output. Practice has shown that grain is an important economic advantage of Jiangsu. We must continue to make use of this advantage and in no way weaken it.

Under the new situation, however, some comrades have had muddled thinking about whether or not to continue to pay close attention to grain production or to strive for continued stable growth in grain output. Some feel that the grain problem has already been solved basically and that the most pressing task now is to increase economic income, producing an attitude of "go for money, not for grain." It is proper to strive to increase the economic income of the collectives, but we definitely cannot as a result weaken grain production. Because the people of Jiangsu did away with the interference and sabotage of the Lin Biao and Jiang Qing counterrevolutionary cliques, our grain production situation has been relatively good since the 1970s. In general, however, our grain output level is still low and still is far from meeting the needs of national economic development and continual improvements in the standard of living. Last year was the second highest bumper grain harvest in Jiangsu since liberation, but it was only 770 jin per capita. The situation is rather tight in various aspects. Matters have even gotten a bit more difficult in some places where grain has fallen consecutively over the past two years. Therefore we cannot let up in the slightest on grain production.

Some comrades set the development of grain and of economic diversification in opposition to each other, claiming that "if grain does not go down, it is hard for diversification to come up; and if economic diversification is to go up, grain production must come down." These comrades ignore the mutual reinforcement and promotion of grain production and economic diversification. Our basic guiding policy in agricultural development is "in no way relax grain production while actively diversifying economically." We must carry it out in a comprehensive manner. Grain output must persist in increasing and diversification must also develop further. There is still a great potential for economic diversification. Barren mountains, earthen hillocks and water surfaces in many places are not yet utilized thoroughly. Thus it is entirely possible to strive to maintain a relatively rapid development of a diversified economy at the same time that great efforts are expended on guaranteeing a stable growth in grain. In developing a diversified economy, we definitely cannot fix our eyes on the grain fields and occupy any more of them to change over to economic crops. The peasants desire prosperity and to increase their incomes, but this cannot be done by tossing out grain production. If grain production is not done well, it is impossible to diversify the economy as well. At present, some places cannot guarantee a supply of fodder because grain is too short. The development of feed has already been affected. This is worth thinking deeply about. In sum, if grain does not go up it will affect arrangements for people's livelihood, economic diversification and the development of the entire national economy. This is an enormous problem which is not only economic but also political. Leaders at all levels, including brigade and team cadres, must keep a clear head about this.

Other comrades say that we must respect the production teams' right of self-determination. Cropping plans are determined by the production teams, so whatever everyone wants to grow is what is planted. This opinion is also one-sided. The party's policies stipulate that the production teams, persisting in a socialist direction, should carry out the policies, laws and decrees of the state and, under the precondition of receiving the leadership of the state plan, plant in keeping with local conditions. This does not mean planting whatever one thinks of. Grain is a principal product which affects the national economy and the people's livelihood and its production should be carried out according to the leadership of the state plan. At present, all parts of Jiangsu have already done large-scale contracting of state grain purchase quotas. This contracting per se embodies the plans of the state and has a directive nature. The contracted quotas must be resolutely fulfilled. When each locality arranges its cropping plan it must first of all consider

When each locality arranges its cropping plan it must first of all consider the fulfillment of the contracted grain quotas. This must be a precondition for making good arrangements for agricultural production.

In striving for a stable increase in grain production we must first of all stabilize the cultivated and sown areas of grain. At the present level of technology, grain output cannot increase stably without guaranteeing it a certain acreage. It is necessary to make appropriate readjustments in the grain acreage in a planned way in order to develop economic crops. In the past several years, our province has already made a large readjustment in agricultural arrangements, resulting in a considerable decline in cultivated and sown grain area. Now the internal structure of agriculture tends to be rational in general. Therefore we must rely in the main on increases in yields per unit area and on opening up as yet unutilized resources when we develop our economic crops. We definitely cannot put the squeeze on any more grain land. The spatial arrangement of grain crops this year should be set at last year's level and the sown area of grain cannot be reduced any further. The summer-ripening crops are already in the fields, so the key is in allocations for spring sowing. Every locality must get a good handle on this.

Guaranteeing a stable increase in grain is the glorious mission of the broad masses of rural cadres and peasants in the villages of our province. Each locality must proceed from reality in making arrangements. In particular, it must stabilize and perfect the various forms of production responsibility systems. The Taihu basin is the principal commodity grain base of Jiangsu. It should persist in taking agriculture as its basis and use industry to supplement agriculture, sidelines to promote it, guaranteeing and stabilizing the labor power devoted to growing grain by further mobilizing their activism so that they use every possible means to bring grain production up. The Lixiahe area is the belly of Jiangsu, with fertile soil and a large potential for output increases. It should guarantee that grain production continues to increase on the basis of its successive years of bumper harvests. The Xuhuai area has come up rapidly in recent years and should further unearth its potential and make more contributions through increasing grain output.

JIANGSU AGRICULTURAL SCIENTISTS INVESTIGATE WHEAT FIELD MANAGEMENT

Nanjing XINHUA RIBAO in Chinese 21 Jan 82 p 1

[Article: "Pay Close Attention to Current Wheat Field Management"]

[Text] Comrades of the Wheat Cultivation Laboratory of the Jiangsu Institute of Agricultural Science recently worked together with agricultural scientists and technicians of the provincial Department of Agriculture and Forestry; Yanziji Commune, Nanjing Municipality; Xinba and Lianhe communes, Yangzhong County; and Agricultural Bureau and Furong Commune, Wujin County to carry out an inspection of the overwintering crop conditions at several model units in the Zhenjiang hilly wheat region, the wheat region along the Chang Jiang and the Tai He wheat region, looking at their intermediate experimental demonstration plots in high-yield cultivation of the "three wheats" [wheat, barley and oats]. They checked out the conditions of the crops and of winter management on the larger fields as well, and studied measures for field management.

The general characteristics of "three wheat" production are as follows: A sufficient area has been planted, basically the number of sprouts exceeds previous years, and in wheat field management, activities have been prompt and down-to-earth, with good quality and a fast pace. Nonetheless, during the sowing stage last fall, the percentage of soggy cultivation and planting was large and the season was delayed, producing relatively more late sprouts, dragging out the evening up period when the sprouts appeared as temperatures were low, delaying the pace of leafing and tillering. From last November to date there has been a long drought, preventing the wheat sprouts from growing strong during the winter. With these conditions where excess surface water was followed by drought and low temperatures, several problems have arisen to affect the "three wheats." First, growth before the winter was at a minimum, with an insufficient number of sprouts and poor quality. From mid-October to the end of November, precisely the most critical sowing period, there was unfavorable weather prolonging the sowing period. Autumn sowing was not completed in the southern Jiangsu area until the end of November. After the sowing was complete there was continuous low temperature drawing out the evening-up period of the sprouts, with slow leafing and tillering, further limiting the amount of growth.

Second, drought affected winter strengthening and development. In wheat fields which received neither rain nor irrigation water for a long period, the water content of the soil from 0-5 cm was only 6.7 percent, and that of the tilled layer from 5-15 cm was but 4.1 percent. This seriously affected the rooting, leaving and tillering of the wheat sprouts. The area of tiller-bearing overwintering sprouts was greatly reduced this year, being only 35 percent in Yangzhong County and 30 percent in Wujin County, the latter a reduction of 28 percent over the same period the previous year.

Third, the unevenness of the sprout conditions is relatively widespread. Some cadres in the commune sector who have problems in understanding how to implement the production responsibility systems have relaxed their leadership over current production. Some commune sector comrades have paid more attention to managing industry and diversified economic operations and have relaxed wheat field management.

Given these current crop conditions and problems, the agricultural technicians participating in the inspection made the following proposals. First, apply fertilizer to promote strengthening and strive for winter development. Closely tend to field management before the spring, with a topdressing on the early crops to promote growth and strive for winter development and a uniform application of liquid fertilizer on the late crops to maintain full stands of seedlings through the winter and strive for lower level tillering in the early spring, working in every way to increase the total number of seedlings and strive for a high production of ears. Second, promote the seedlings in resisting drought and use water to transfer fertilizer. We must take advantage of the present favorable opportunity of the higher temperatures to apply fertilizer rapidly to resist drought, using more water than fertilizer and using the water to transfer the fertilizer and energetically promote winter development. Places with suitable conditions should thoroughly utilize sprinkler irrigation. Places without sprinkler irrigation should fill the outer three ditches with irrigation water using irrigation and drainage machinery and then carry water to sprinkle the fields, being sure not to flood the fields, creating a hardpan which would kill the seedlings. Third, loosen the soil and eliminate weed dangers. Taking advantage of the clear weather, we should weed and loosen the soil, aerating it and increasing its temperature so as to eliminate weeds and promote sprout development. The weed danger must be eliminated before the spring or weeds will flourish later, possibly leading to large areas being taken over by weeds, inducing pest infestations and causing a reduction in output. Fourth, tamp down the wheat and clean out the ditches to regulate soil moisture. Places with appropriate conditions should apply a layer of mud to cover the roots of the wheat and protect the tillering joints. Most of the fields should have a general tamping or pressing down of the wheat, with the upturned soil broken up to close the cracks in the soil and cover the tillering joints, improving the conditions for root system growth and protecting the wheat seedlings in overwintering.

The standards for complete sets of field ditches in the wheat fields have fallen this year compared with the past. Places which have assigned output quotas to individual able-bodied laborers have even more variable conditions. In order to prevent spring waterlogging, they must at the same time do a good job of taking care of soil moisture and putting ditches in order.

SUZHOU WINTER CROP MANAGEMENT SUCCESSES RECOUNTED

Nanjing XINHUA RIBAO in Chinese 19 Jan 82 p 1

[Article by the Reporting Station, Suzhou Administrative Office: "Suzhou Prefecture Strengthens Management of Overwintering Crops"]

[Text] Winter crop field management in Suzhou Prefecture has been done on time this year and seedling conditions are generally good. As of the beginning of this month, over 80 percent of the prefecture's 3.59 million mu of "three wheat" [wheat, barley and oats] fields have had additional labor applied to pressing down the wheat, had a topdressing of cured fertilizer and had ditches cleaned to regulate soil moisture. The soil has been loosened and heaped around the roots, together with a topdressing of fertilizer on over 80 percent of the 1.1 million mu of rapeseed. Many communes, brigades and teams in Kunshan, Wujiang, Taicang, Wuxian, Wuxi and Jiangyin counties have restored the old tradition of irrigating with river silt. This was seldom done in recent years.

This year we got our thinking going early on winter field management in Suzhou Prefecture, with the leadership at all levels being relatively clear about the leading thinking of taking agriculture as the basis. By linking it with honoring its commitments on distribution and encouraging the masses to do a good job of current production, both the pace and quality of winter field management has exceeded previous years in Kunshan County. Wu County has made full use of its model, Hongxing Brigade of Huangdai Commune, to fan a quick upsurge in field management. Some advanced units, such as Huaxi Brigade in Jiangyin County, have already wrapped up their field management of summer-ripening crops. Many communes, brigades and teams have also done a crash job of doing supplementary management of wheat which was planted in damp, muddy soil and of the three kinds of seedlings so as to promote a transformation and balance. After a period of crash work, 45 percent of the 690,000 mu of three kinds of seedlings of the three wheats in the prefecture have been transformed and upgraded.

PRC TRAINING FOREIGN FISHERY TECHNICIANS

OW151137 Beijing XINHUA in English 0751 GMT 15 Apr 82

[Text] Beijing, April 15 (XINHUA)--The second fresh-water fish breeding technique training course for technicians from developing countries opened today in Wuxi, Jiangsu Province, according to the state administration of aquatic products.

The four-month course is sponsored under a cooperation plan between China and the United Nations development program. The nine trainees are from Burma, Malaysia, Pakistan, Papua New Guinea, Sri Lanka and Thailand. The first course ran from June to October 1981.

The trainees will study controlled breeding in fish hatcheries, development of new fish strains, fish breeding and management and prevention of fish diseases. Experts from the Yangtze River Aquatic Products Research Institute will lecture on the techniques to promote fishery, crop growth and poultry and domestic animal breeding. Trainees will do field work in Guangdong Province.

China's 1981 fresh-water fish catch came to 1.37 million tons, ranking first in the world. In recent years, Chinese fish breeding experts have passed on techniques to their counterparts in the developing countries. Experts from Britain, France and the United States have also studied fresh-water fish breeding in China.

Since 1975, China has trained 159 fishery officials and technicians from developing countries, according to the state administration of aquatic products.

CSO: 4020/120

BRIEFS

AQUATIC PRODUCTS INCREASE IN JIANGSU--Aquatic products enterprises have continued to grow in Jiangsu Province during the past year. Output of aquatic products has overfulfilled plan and has set an all-time high; aquatic products procurement plans have been overfulfilled; and quantity of aquatic products sent to market has increased. Last year all echelons of government further strengthened leadership of aquatic products work. Everywhere mentality was emancipated and policies liberalized in water surface use rights, in programs for development of aquatic products, and in methods of administration. Reliance was placed on science and attention was given arousal of positive factors everywhere, thereby gradually bringing about improvements in the fishing industry's structure for production, its system of administration, and channels of circulation. Pace of growth in the raising of freshwater fish accelerated, the raising of fish by production teams and households receiving particularly serious attention. The freshwater fish raising area in the province was increased by more than 100,000 mu over what it had been in 1980, and output increased by nearly 120,000 tons, making 1980 the year of greatest increase in production during the past few years. Simultaneous with the stringent efforts made in aquatic products production, all levels of aquatic products units devoted attention to doing a good job in procurement, supply, and marketing of aquatic products. [Text] [Nanjing XINHUA RIBAO in Chinese 22 Jan 82 p 2] 9432

HOG RAISING--Nanjing, 6 Apr (XINHUA)--Jiangsu has seen an upturn in hog breeding. The number of hogs in stock in January and February increased by 1.5 million head over the corresponding period last year. Over the past few years, Jiangsu has sold the state 17 million to 18 million hogs each year. [Beijing XINHUA Domestic Service in Chinese 0114 GMT 6 Apr 82]

BRIEFS

ANYUAN COUNTY EARLY RICE--Transplanting of early rice seedlings is underway in Anyuan County, Jiangxi. The county will grow 153,000 mu of early rice this year. As of mid-April, about 40 percent of the transplanting was completed. [OW251325 Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 21 Apr 82 OW]

FENGCHENG COUNTY SOYBEANS--As of 17 April, more than 96,000 mu of land had been planted to early soybeans in Fengcheng County, Jiangxi, an increase of 9,000 mu over the same period last year. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 21 Apr 82 OW]

CSO: 4007/375

BRIEFS

PROVINCIAL SOWING--As of 15 April, Jilin Province had planted 3,525,000 mu of wheat, minor oil-bearing crops and various field crops, 450,000 mu more than in the corresponding 1981 period. Some 124,000 mu of paddy rice seedlings had been grown, accounting for over 40 percent of the paddy rice seedling plan. [SK171420 Changchun Jilin Provincial Service in Mandarin 1100 GMT 16 Apr 82]

WET GRAIN DISPOSITION--Grain departments at all levels throughout Jilin Province are drying wet grains in a timely manner. As of 30 March, the province had dried 40 percent of grains with high moisture content by taking advantage of the dry spring season. Of the grains stored last year, 4 billion jin require drying this spring. Therefore, the province urges departments concerned to complete their drying work before 10 May, the start of the rainy season. [SK072207 Changchun Jilin Provincial Service in Mandarin 1100 GMT 6 Apr 82]

GRAIN PRODUCTION--Grain output in Jilin Province in 1981 was 18.44 billion jin, up 7.3 percent over 1980 and an increase of 150 million jin over the record figure of 1978. The average per mu yield was 350 jin, up 12 jin over 1978. Six localities, not including Changchun, increased output. The income of the rural basic accounting units increased 418 million yuan over the best figure in 1980, an increase of 12.6 percent. Net income for distribution was 2.44 billion yuan--an increase of 343 million yuan over 1980, of which 1.98 billion yuan went to commune members, an increase of 20.6 percent over 1980. The average per capita income was 144.1 yuan, up 26.6 yuan, an increase of 22.6 percent over the previous year. Six localities in the province increased income. Municipalities and counties with an average per capita income over 150 yuan increased from 6 in 1980 to 25. Communes with an average per capita income over 200 yuan increased from 27 in 1980 to 139. [SK132247 Changchun Jilin Provincial Service in Mandarin 2200 GMT 12 Apr 82]

SCIENTIFIC FARMING--Fuyu County has applied scientific methods to farming and has planted 495,000 mu of crops. County cadres at all levels, along with scientific workers, have conducted a survey on soil composition in 37 brigades, urging all production teams to apply chemical fertilizer to crops in light of different soil compositions. [SK200801 Changchun Jilin Provincial Service in Mandarin 1100 GMT 19 Apr 82]

CSO: 4007/382

BRIEFS

COLLIERY FORESTS--Collieries in Liaoning Province have built shelterbelts in mining areas for many years. Now these collieries have a forest acreage of 1.81 million mu and 2.7 million cubic meters of timber storage. From 1977 to 1981, 420,000 mu of shelterbelts were built and over 75 percent survived. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 4 Apr 82]

PROVINCIAL CROPS--Over the past 3 years, the Liaoning Provincial Academy of Agroscience has developed 12 new crossbred types of paddy rice, corn, sunflower and cucumber and produced 620,000 jin of seeds of these new breeds. (Yuyao) No 57, a crossbred variety of paddy rice which won a national prize, has been cultivated on 2.2 million mu in the past 3 years in Liaoning, Shandong, Shanxi, Henan, Hebei, Jiangsu, Beijing and Tianjin provinces and municipalities. Output has generally increased over 10 percent, contributing an additional 275 million jin of paddy rice. The province last year cultivated 490,000 mu, half of the province's sunflower acreage, of Liaokui No 1 sunflower breed. The result was good. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 12 Apr 82]

NATIVE, LIVESTOCK PRODUCTS--By the end of March, the value of native and livestock products purchased by supply and marketing cooperatives in Liaoning Province were respectively 16.5 percent and 13.2 percent higher than in the corresponding 1981 period. [SK171424 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 16 Apr 82]

AGRICULTURAL LOANS--Agricultural banks and credit cooperatives in Liaoning Province have granted loans to support spring farming. By the end of March, the province had granted agricultural loans totalling 626 million yuan, an increase of 10 percent over the corresponding 1981 period. [SK132248 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 12 Apr 82]

CSO: 4007/382

BRIEFS

VEGETABLE PRODUCTION--The regional people's government recently issued a circular urging efforts to strengthen vegetable production and marketing work to ensure vegetable supplies this year. The circular states: Suburban areas should focus their production on vegetables. Suburban areas in the west should assign 7 li of vegetable fields to each vegetable farmer. Suburban areas in the west should assign 8.1 li to 1 fen to each. The retail prices of vegetables should be frozen. Vegetable producing brigades will be compensated by local financial departments for deficits in vegetable production. Effective measures should be adopted to eliminate deficits caused by poor management. [SK080439 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 7 Apr 82]

EGG PROCUREMENT--As of early April, Nei Monggol had procured 2.09 million jin of eggs, up 96.5 percent over the corresponding 1981 period. Chickens raised by commune members totaled 13.49 million, an increase of 1.94 million. [SK190930 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 18 Apr 82]

PROBLEMS WITH APATHY AT GRASSROOTS LEVEL DISCUSSED

Beijing ZHONGGUO NONGMIN BAO in Chinese 7 Feb 82 p 1

[Article by Bi Bingjian [3968 4426 7003], Deputy Chairman, Ninxia-Hui Autonomous Region, Farming and Forestry Office: "Several Problems in Perfecting Systems of Responsibility"]

[Text] Throughout rural Ningxia, systems of responsibility have been established, most of them being systems of responsibility whereby work tasks are contracted to individual households. These are now entering the state of summation, perfection, and stabilization. A look at the situation in Ningxia shows several problems in perfecting systems of responsibility that merit discussion and study.

1. 1. How Can the Socialist Collective Road Be Adhered to?

Generally speaking, there are two roads for maintenance of the social collective economy. The first is public ownership of the means of production such as land, and the second is distribution on the basis of work. There is no doubt about this, but what else can be done?

I believe that the socialist collective economy also has to achieve a common prosperity. Following liberalization of policies, those with a head for economics, those with skills, and those with ability are able to become prosperous first. However, those who know nothing but farming the land, who lack special skills, and who are not good at economic diversification, and particularly those households with few working members, find it difficult to become prosperous. Those who lead have to encourage not only "outstanding households," but also to support hardship households. In newspaper propaganda, bank loans, scientific and technical guidance, and provisions for people livelihoods, attention has to be directed to this problem.

The socialist collective economy also has to be a planned economy. We acknowledge the role of the laws of value; however, it has to be made clear that in China's agriculture, it is planned economy that is paramount and market regulation that is supplementary. Rural communes and brigades have to have an overall conception and handle well the relationship between planned guidance and self-determination. They cannot simply consider what to grow on the basis of what brings the greatest profits, and fail to implement state plans. Departure from the guidance of state plans can produce blindness. Not only rural communes and brigades, but economic units concerned, as well, have to study methods to be used to practice planned guidance. Institution of a contract system is a fine method; however, contracts do not have to be made into assignment books; contracts should provide both rights and obligations for both parties.

2. How Should the Grassroots Handle Matters?

In rural villages, communes and brigades constitute the foundation. Implementation of CCP Central Committee policies depends on the grassroots. Many production team heads had no idea for a long time as to how the grassroots should manage affairs once Ningxia had established systems of responsibility for production. Some places formulated 10 regulations for their grassroots cadres, but real management cannot be done that easily. I believe that for production team heads the main rule must be to do things for the commune members. When you do good things for commune members, the commune members will be happy and will manage things well. Institution of systems of responsibility for production can produce a one-third surplus of rural workforces. Organization of this workforce for economic diversification for greater production and greater earnings constitutes the main job of the production team heads.

Today there is concern about maintenance of social order from top to bottom. In some places public order is not all it should be for reasons of two kinds. One is that the effects of 10 years of turmoil have not yet been thoroughly purged, and the other is that grassroots political power plays no role. In such a situation, it is not enough to rely solely on public security personnel for the maintenance of social order in rural areas. There has to be reliance on grassroots political power, a strengthening of ideological and political work, and arousal of the masses to vigilance. Today some grassroots cadres do not want to take responsibility, fearing that if they don't discharge their duties well, they will themselves violate the law. Such ideas have to be rooted out. In another realm, political and legal units should clearly formulate several regulations covering matters to be the concern of grassroots political power so that they can be abided by. All problems that can be solved at the grassroots level should be solved at the grassroots level.

In order to make the grassroots assume the economic functions and political functions they should assume, it is necessary to solve the problem of how grassroots cadres are regarded. One must say that an overwhelming majority of grassroots cadres are good or comparatively good, and that those with a bad work style are in the minority. When grassroots cadres' ideas momentarily lag behind events, some people say that cadres are "props that hold doors shut." Such a statement is not fair. Implementation of systems of responsibility is a process, and the perception of cadres is a process too. Cadres must be allowed to constantly summarize experiences during the process of practice and gradually improve their perceptions. They must be helped, believed in, and relied upon to handle grassroots matters well.

3. How Can Farm Produce Prices Be Controlled?

Price policies have a great effect on agriculture. When prices are set too low, the peasants do not make money and do not want to produce. When they are set too high, production is stimulated, but sales are hurt. Several kinds of products in Ningxia currently face this latter problem. Some economic units continue to use the old methods, raising prices inappropriately on these things, with the result that overproduction occurs but the goods cannot be sold. Then they limit purchases from producers. This is extremely bad for planned, proportional development of production. A policy of basic stability must be followed for farm produce prices. Getting of procurement prices to be paid for various agricultural products must be commensurate with their value. There has to be equitable price parity, consideration of market demand, mostly the demand in the national market, and doing what will both stimulate production and help sales.

BRIEFS

HAIDONG PREFECTURE GRAIN AREAS--Following the institution of responsibility systems, communes in Haidong Prefecture, Qinghai, blindly increased the acreage of oil-bearing crops and vegetables. Haidong prefectural civil administration has corrected this trend in a timely manner. Now the prefecture's grain areas are maintained at 3.7 million mu, and its oil-bearing crop areas are maintained at 400,000 mu. The prefecture's grain and oil-bearing seed procurement targets now can be fulfilled. [SK060645 Xining Qinghai Provincial Service in Mandarin 1100 GMT 4 Mar 82]

CSO: 4007/382

BRIEFS

SUMMER FIELD MANAGEMENT--On 18 and 19 March, comrades of the Shaanxi Provincial Agricultural Committee, the provincial Agricultural Bureau and the provincial Agricultural Scientific Research Center and some agricultural scientists inspected the growth of wheat in the fields in Yangling and (Zhaijia) communes in Wugong County and held a forum on specific measures for current summer field management. The experts and professors attending the forum held that in the light of the situation of the growth and the development of wheat in the Guangzhong area, the province should do well in irrigating wheat fields, applying manure, weeding and tending rape and cotton. [HK301349 Xian Shaanxi Provincial Service in Mandarin 2300 GMT 23 Mar 82]

COMMENTARY ON WHEATFIELD MANAGEMENT

SK170738 Jinan Shandong Provincial Service in Mandarin 2300 GMT 16 Apr 82

[Station commentary: "Do a Good Job in Strengthening Middle and Late Stage Wheatfield Management"]

[Excerpts] The ear and straw of wheat now are coming out. It is an important period for reaping a good wheat harvest. Leaders at all levels and the broad masses of commune members should adopt effective measures to conduct middle and late stage wheatfield management to ensure a good harvest. Since the beginning of wheat sowing this year, our province has suffered from sustained droughts that have affected the growing of wheat seedlings. However, thanks to good field management in the early spring, wheat growing has taken a favorable turn. So long as we continue to strengthen wheatfield management in the middle and late stages, we can have good harvests.

Some units are not confident of reaping a good wheat harvest this year. Some even think that this year our province will certainly suffer from a reduction in wheat output and therefore slacken their efforts to manage wheatfields. This idea is wrong and should be overcome. There remain 2 months until the wheat is harvested. This is a critical time. It is also a time in which natural disasters occur. The success or failure of field management will decisively affect wheat harvests. Therefore, we must correct our ideas, enhance our spirit, foster confidence and adopt effective measures to strengthen the middle and late stage wheatfield management. We should have good field management to ensure a good harvest.

Emphasis should be on the management of high-yield wheatfields. Wheat seedlings on the province's 30 million mu of high-yield plots are growing well. Therefore, our province has great potential to increase wheat output. We must try all possible ways to ensure proper irrigation and topdressing to harvest more wheat. Meanwhile, equal attention should be paid to strengthening the management of common wheatfields to fulfill and overfulfill this year's wheat production plan.

CSO: 4007/382

BRIEFS

PROVINCIAL IRRIGATION--Taking advantage of the Huanghe River diversion project, Liaocheng Prefecture has irrigated 2.16 million mu out of its 2.5 million wheat fields and 3.36 million mu of its 4 million mu of cotton fields. [SK171408 Jinan Shandong Provincial Service in Mandarin 2300 GMT 16 Apr 82]

PROVINCIAL AFFORESTATION--By 5 April, Shandong Province had prepared 0.22 million mu of lands for afforestation, built 0.49 million mu of forests and 2.44 million mu of shelterbelts around farmlands, interplanted tung trees and grain crops on 1.45 million mu of farmlands, planted 174 million trees around houses and lakes and on the sides of roads, planted 66.5 million tons of bushes and built 0.1 million mu of nurseries. [SK190840 Jinan Shandong Provincial Service in Mandarin 2300 GMT 18 Apr 82]

SEED STRAINS--In the past few years, 70 varieties of fine seed strains developed in Shandong Province have been commended by national departments concerned. In 1981, some 127 million mu--93 percent--of major crop fields were sown with fine seed strains. However, due to bad methods and irrational distribution, the management and utilization of these seed strains are poor and disorderly. To counter this, it is necessary to establish organizations for selecting and popularizing good quality seed strains to manage and utilize these seeds scientifically and systematically. [SK122217 Jinan Shandong Provincial Service in Mandarin 2300 GMT 11 Apr 82]

APPLICATIONS OF ISOTOPE, RADIOACTIVE TECHNOLOGY DISCUSSED

Shanghai WEN HUI RIBAO in Chinese 19 Jan 82 p 1

[Article: "Use of Atomic Energy to Benefit the People. Radioactive Breeding Methods Can Change Farm Crops Into "Trees That Shower Money." Use of Nuclear Technology Provides Appreciable Economic Benefits to Industrial Production"]

[Text] News from units concerned reports that during the past few years China's atomic energy science and technology has actively served the national economy to win appreciable benefits for it.

Agricultural science has widely applied isotope and radiation technology. Already 150 new varieties have been bred through use of radioactive breeding methods including grain, cotton, oil-bearing crops, fruits, and vegetables, which have been extended over an area of 100 million mu annually. From grain alone annual increase in output has been 5 billion jin. Increased accumulated earnings over a period of several years from radioactively bred "Lumian No 1" [cotton] have been 1.9 billion yuan, and the Shandong peasants called it "a tree that showers money." "Yuanfengzao" paddy rice has been extended to cultivation over a cumulative more than 70 million mu for an increase in output totaling 4 billion jin. New methods of applying fertilizer have been successfully developed through isotope tracer technology, increasing the chemical fertilizer utilization rate by 20 percent. Some valuable achievements have been won in radioactive sterilization of insects, research on chemical fertilizer synergists, radiation of food for storage, and safe use of pesticides. Industrial applications of isotope technology and radiation technology are becoming increasingly great, notably in the measurement of thicknesses, densities, and position of materials [2436 0143], in non-destructive flaw detection, in leak detection, in neutron activation analysis, in radiochemistry, prospecting for geological resources, static electricity elimination, and fire alarms. Rolling mill use of isotopes to measure thicknesses has brought about control over thicknesses of steel plates, thereby making manifold increases in the rate of steel plates meeting specifications. By using an isotope thickness measuring device, the Baoding Paper Mill produced 220,000 yuan earnings per machine per year. The Haerbin Petroleum Refinery's use of an isotope materials position instrument [2436 0143 6060] permitted manifold increases in the petroleum recovery rate. Use by a Taiyuan rolling mill of nuclear technology produced remarkable economic results.

Promotion of radiation processing technology in the organic chemical industries of Shanghai and other places has developed a group of new products with very broad uses.

During the past several years, application of nuclear technology to medicine has developed very quickly. Nuclear medicine has spread to every province, municipality, and autonomous region except Tibet. More than 900 hospitals and research units are using it, and there is a specialized nuclear technology corps totaling 4,000. Various kinds of radioactive medicines and instruments have developed very rapidly, and great strides have been made in their use for diagnosis of cancers, cardiovascular disease, and disorders of the thyroid gland. By way of promoting further use of isotopes in the national economy, the State Science Commission, the National Defense Science Commission, the China Science Society, and the two ministries of machine building have decided to convene a "National Conference on Isotopes" within a short period of time.

BRIEFS

CIRCULAR ON PIG-RAISING--The regional people's government issued a circular on 9 April on vigorously promoting pig-raising. The circular said: The region must take two steps to solve its problems in pork production and supply. In the first step, we must strive to become basically self-sufficient in pork by 1985. In the second step, we must achieve complete self-sufficiency. The circular demanded that the region get a good grasp of pig-raising and assign procurement quotas. It is necessary to implement the policies and actively encourage the peasants to raise pigs while consolidating and developing collective pig-raising. TITLE: "Survey of Condition of Extension of the Method of Eliminating Intermediate Cultivation for Cotton"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 2, 1982 p 19

ABSTRACT: In the past 3 years, the Luancheng County Agricultural Modernization Comprehensive Scientific Experiment Foundation has been extending the method of eliminating intermediate cultivation for cotton crops, which is a fruit of research, jointly by the Institute of Genetics and the Shijiazhuang Agricultural Modernization Institute of Chinese Academy of Sciences. According to the 14-commune statistical survey of 1980, the 24,000 mu of cotton for which the method was adopted, averaged a yield increase of 10-15 percent. The method made it possible to seed about 10 days earlier, caused the soil temperature to be 2°C higher, reduced the density of cotton plants, saved labor, used less water before blooming, needed very little seedling fertilizer, brought about early development of seedlings, and lessened pest damage. Not a few cotton fields yielded close to 200 jin of ginned cotton/mu. The paper does not include a description of the method, however.

ORG: Yangzhou Prefecture Rice Disease Resistance Breeding Cooperative Group, Jiangsu Province

TITLE: "New Line of White Withering Resistant Intermediate Xian Rice, 910, 929"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 2, 1982 p 20

ABSTRACT: White withering disease has become a great obstacle for the development of rice production in Yangzhou. In the 12 years of 1970-81, there were 2 years of severe epidemics and 4 years of lesser epidemics resulting in losses varying from 70-110 million jin of rice a year. A research project has been carried out by the Prefecture Institute of Agricultural Sciences to breed from the BG-90-2 system, 2 resistant strains, 910 and 929. Experimental cultivation was conducted in Yizheng County etc. to confirm their white withering resistance. They were found to mature about 15 days earlier than BG-90-2, with yield varying from 900 to 1,100 jin/mu, obviously higher than that of local breeds. The disease resistant manifestations, the high yield properties, and the adaptability of the new strains of 910 and 929 are described. At present, the supply of seeds of 910 and 929 is very limited, limiting to 1-2 jin per order at a price of 0.15 yuan/jin with an additional 1 yuan to cover postage.

TITLE: "Growth and Development Characteristics of Intermediate Maturing Early Xian Rice 77-6"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 1, 5 Feb 82 pp 7-8

ABSTRACT: The early rice strain 77-6 was bred out by the institute from a single spike, an offspring of Kefuzao x Zhulianai, with nitrogen molecule laser treatment. The first generation (1976) matured 3 days earlier, the spike became longer, and the plant appeared in a tighter shape. It was propagated in the winters of 76-78 in South China. Experimental production of 79-80 indicated an average yield of 915.04 jin/mu, following crops of green manure or vegetables, 846.4 jin/mu, following barley or naked barley, and 804.9 jin/mu following rape or rice seedbeds, amounting to increases of 6.31 to 10.93 percent over the control breed, Yuanfengzao. The major characteristics of 77-6. including a well-developed root system of seedlings, early tillering, numerous effective spikes, standing leaves to permit high utilization of photo-energy, good ventilation, only mildly susceptible to sheath and culm disease, high rate grain yield, good rice quality, and high protein and amino acid contents are discussed. With the same yield as Yuanfengzao but maturing 3 days earlier, it provides a favorable condition for early transplanting of the late season rice and thus the condition for a triple crop system.

'RENMIN RIBAO' DISCUSSES FARM PRODUCTION IMPROVEMENT

HK260759 Beijing RENMIN RIBAO in Chinese 20 Apr 82 p 2

[Commentator's article: "Strive To Improve the Conditions for Farm Production"]

[Text] Having become rich economically, the peasants in Huaiyuan County of Anhui Province and Xinyi County of Jiangsu Province have begun to actively invest labor and capital in improving the conditions for production, so as to push ahead with the continuous development of agriculture. This is really a foresighted and sagacious step which should be popularized.

In the last few years, as the responsibility system of linking remuneration to production has been implemented in rural areas, production has developed rapidly and the savings of quite a few peasants have increased. How should one rationally employ the grain and money that has been saved. This problem calls for careful study. The vast number of peasants have learned from their own experience that because of the party's correct policy and the people's great initiative, agricultural production has been increased in the last few years. They know that this is the most important factor for developing production. They also know that promoting production cannot go without certain material and technical conditions, such as the improvement of material conditions, the enhancement of scientific and technological levels of water conservancy, manure production, fine variety breeding, plant protection, farm machinery production, storage and transportation, and so on. If these conditions are lacking, agricultural production will not be able to move forward steadily and continue to develop. In some places which frequently suffer from natural disasters, the farmland's ability to resist disaster is weak, and continuous improvement of the conditions for production is particularly important for the steady development of agricultural production.

In order to improve the conditions for agricultural production, the state will provide some material and capital assistance. However, in the period of economic readjustment, there will not be a large amount of state aid. Thus, funds and materials must be allocated to key projects and must not be used in a scattered fashion. Therefore, in order to improve the conditions for agricultural production, production brigades and teams in various places still have to depend on themselves in raising funds. At present, this calls for the correct handling of the relationships between accumulation and consumption and between the enhancement of living standards and the development of production and construction. In the past, peasants in some places were living in poverty for a long time, and now they are becoming rich. So, they renovate their houses, buy more daily necessities, try to eat better and dress better, and improve their lives materially and culturally. This is quite reasonable. However, when improving livelihood, we must have our eyes on the future, and keep long-term construction in mind, so as to ensure that agriculture can develop steadily. "Feed the people first and then promote construction." If we do not allocate some funds to developing production and construction but use up all the funds on food and consumption, there will be stagnancy in production, and the cause of continuously developing agriculture will be hopeless. Only by persistently giving play to the fine tradition of being self-reliant and working hard, accumulating more funds, and continuously expanding reproduction, can we create more social wealth and thus further improve the masses' livelihood. Our peasants understand this. What the peasants in Xinyi County said is quite right: "Although our income has been increased, we must not be concerned solely with eating and drinking. On the contrary, we have to save money for the future!" The peasants of all brigades and teams in rural areas must have such an understanding too, and they should follow the example of the peasants in these two countries.

The experiences of Huaiyuan and Xinyi counties show that the latent power in agricultural development is great. There are plenty of things to be promoted in rural areas. The leading cadres at different levels must try to skillfully guide and organize the masses, assist communes and brigades in working out long-term plans, and help peasants properly run all aspects of their business activity. On the other hand, they should provide peasants with the necessary assistance so as to mobilize the latter's initiative in investing labor and capital in developing production. The peasants' interests must be protected, the decisionmaking power of production teams must be respected, arbitrary and impracticable directions must be avoided, and the practices of egalitarianism and indiscriminate transfer of resources must be eliminated.

As various forms of the production responsibility system are being gradually amplified and the conditions for production are continuously improved, we can be sure that agricultural production will further develop this year.

EFFECTIVENESS OF NEW SYSTEM FOR FORESTRY APPARENT

Beijing ZHONGGUO NONGMIN BAO in Chinese 31 Jan 82 p 1

[Article by Lin Guan [2651 6306]: "Localities Throughout the Nation Have Realized Results in Implementing the Three Establishments System"]

[Text] Up to the end of last year, the work of "three establishments" --establishing and stabilizing rights of mountain forests, zoning private mountains, and establishing the production responsibility system in forestry--has been widely launched in 27 provinces, cities, and autonomous regions (Shanghai and Xizang are preparing to launch the work). The number of counties (cities) that have launched "three establishments" work in forestry has reached 1,695, which is 75 percent of the total number of counties (cities) throughout the nation. Among them, 1,053 counties (cities) have implemented it on an overall basis.

Hunan, Guangxi, Jingxi, Liaoning, and Hebei, which have progressed relatively fast in the work of "three establishments" in forestry, have completed over 30 percent of the tasks. Sichuan Province has completed nearly 50 percent. According to incomplete statistics from Hebei, Liaoning, Fujian, Jiangxi, Henan, Hubei, Hunan, Guangxi, Sichuan, Guizhou, Shaanxi, and Gansu, 47.92 million mu of private mountain land have already been zoned to commune members. Many localities have established or made sound various forms of the production responsibility system in forestry. More than 40 percent of the number of units in the provinces or city of Gansu, Beijing, Sichuan, Hebei, and Jiangxi have established the responsibility system. According to preliminary statistics from Hunan, Guangdong, Jiangxi, Guangxi, and Guizhou, nearly 120,000 various disputes over mountain forest rights have been handled through the work of the "three establishments."

The "three establishments" in forestry have greatly mobilized the enthusiasm of the people and masses in forestration, in cultivating forests, and in protecting forests. At present, the number of trees planted on land in Sichuan Province has reached more than 1.2 billion. Over 70 percent of these trees were planted by commune member individuals. The number of forestfires in the mountain forests of Guizhou Province has been greatly reduced. For example, the area of mountains burned in the Libo County has decreased by about 90 percent from the past.

'RENMIN RIBAO' DISCUSSES USING FARMLAND TO BUILD HOUSES

HK261232 Beijing RENMIN RIBAO in Chinese 19 Apr 82 p 1

[Commentator's article: "Properly Manage the Use of Land in Villages and Townships To Build Houses"]

[Text] Recently, the State Council promulgated the "regulations on management of the use land in the villages and townships to build houses," which reaffirms the party and government's basic policies on land in rural areas and lays down explicit and rational provisions on several questions about the use of land in rural villages and townships to build houses. In a circular, the State Council has demanded that all localities should implement these "regulations" in light of their specific conditions as quickly as possible and should resolutely curb the tendency of abusing farmland in building houses. This is an important item of work in rural areas at present that must not be neglected.

In the past few years, marked changes have taken place in the rural economy. Peasants and collectives of brigades and communes have built many new houses in order to improve living conditions. This is a good thing. However, in many places, this kind of activity, which directly affects the interests of millions of peasants, has not been put on the agenda of leadership work. In addition, there is no unified planning or sound management system in this respect and some cadres are involved in unhealthy trends. Consequently, the phenomenon of abusing farmland in building houses is quite serious. If we do not resolutely and earnestly solve this problem at once, it will do great harm to the four modernizations and to the future generations.

It has been the consistent policy of the party and the government to forbid seizing at will collective farmland of the socialist public ownership. Both the "revised draft resolution and work regulations of the people's communes" adopted at the 10th Plenary Session of the 8th CCP Central Committee in 1962 and the two documents on agriculture formulated at the 3d Plenary Session of the 11th CCP Committee stipulate the following: It is forbidden to rent or sell the land of the production teams, including plots and hills for commune members' private use and plots for building houses and so on; without the approval of government organs at county level, no unit or individual should seize and use land owned by the production teams; areas for commune members to build new houses should be planned by production teams in a unified way and if possible, farmland should not be used. In April last year, in view of the serious situation of destroying farmland to build houses in some localities, the State Council again issued "an emergency circular on putting a stop to using farmland in rural areas to build houses." Why is it that some localities have not yet paid due attention to this problem even after the CCP Central Committee and the State Council have issued repeated injunctions in this respect? One of the important reasons is that leading organs and responsible comrades concerned do not understand very clearly the importance of good management of land. Therefore, they do not do their best to curb this very serious phenomenon of seizing land for building houses at random. Some even close their eyes to this phenomenon. There are also some cadres who take the lead in seizing farmland to building houses, thus creating a very bad impression.

Of course, we should admit that there was no sound and unified system to manage the use of land in villages and townships to build houses. Some difficulties in practical work were also caused by the standard sizes of land for building houses and procedures for obtaining approval, which were not clearly defined. At present, the State Council has promulgated the "regulations" and these difficulties have been removed. Various localities should seize the occasion to seriously work out plans for implementation in accordance with the requirements of the State Council's circular. They should formulate provisions specifying restrictions on using land in villages and townships to build houses, standard sizes for building houses, limitations on authority in giving approval and procedures for giving approval, so that the people will have something to go by and the work will be managed by someone. Moreover, we should make brief plans first and then detailed plans for villages and townships as quickly as possible in order to ensure early implementation of the "regulations" at the basic levels.

The question of using land in villages and townships to build houses is closely related to the interests of the peasants. We should pay attention to carrying out political and ideological work among basic-level cadres and commune members and explain and publicize the spirit of the "regulations" to the masses so that the masses will conscientiously observe them and supervise each other. In this way, the implementation of the "regulations" will be ensured. We should patiently and meticulously persuade and educate the masses and encourage them to take the interests of the whole into account and correctly handle the relationships between the state, collectives and individuals. We should defend the solemnity of the state law and strictly act in accordance with the law. The "regulations" clearly stipulate that anyone who illegally seizes land to build houses shall be punished by returning the land within a specific time, pay a fine or pay indemnities. If the offenders are commune or brigade cadres, or state functionaries, administrative punishment should also be dealt out to them. The State Council's "circular" stresses: Incidences of seizing farmland to build houses that occurred before the promulgation of the "regulations" should also be sternly punished in accordance with the "regulations." We should also investigate and affix administrative, economic and even criminal responsibilities to some cadres who take advantage of their positions and power and engage in malpractices for selfish ends. We should never yield to or tolerate such doings. So long as we resolutely act in accordance with the "regulations," we can certainly change certain disorderly situations in using rural land and gradually systematize the management of land.

BRIEFS

INTERNATIONAL WORKSHOP ON FERTILIZER--Fuzhou, 26 Apr (XINHUA)--The international workshop and training course on nitrogenous fertilizer opened today in Fuzhou, capital of Fujian Province. The 4-day workshop and 19-day course are sponsored jointly by the Fujian Provincial Academy of Agricultural Sciences, the International Fertilizer Development Center (IFDC) and the International Rice Research Institute (IRRI). At the workshop, experts and scholars from 15 countries will exchange their experience in raising the utilization of chemical fertilizer. Chinese experts will brief their foreign colleagues on the techniques of rational use of organic and chemical fertilizer. Chinese and foreign experts will read papers, have discussions and visit Fuzhou and other places. Addressing the opening ceremony were Zhang Gexin, vice-governor of Fujian Province, He Kang, vice-minister of the State Agricultural Commission, Dr P.J. Stangel, deputy managing director of IFDC, and Dr D.J. Greenland, deputy director general of the IRRI. [Text] [OW261516 Beijing XINHUA in English 1506 GMT 26 Apr 82]

MEASURES FOR CONSERVING WATER CANNOT BE SLACKENED

Beijing BEIJING RIBAO in Chinese 29 Jan 82 p 1

[Article by Wang Yonghua [3679 3057 5478]: "The Amount of Water Stored in the City's Two Reservoirs Has Lessened and the Underground Water Level Continues To Drop; Conserving Water To Fight Drought Is Still an Urgent Task and Cannot Be Slackened; Strictly Carry Out the City's Directive on the Use of Water so That the Only Sources of Water Can Be Enough to Supply Water Until Just Before Rainy Season Arrives"]

[Text] This reporter recently learned from the Municipal Water Conservancy Bureau that at present, the drought and the shortage of water in the city have not changed for the better. Conserving the use of water and actively resisting drought are still important tasks for the city's residents and businesses, and they cannot be slackened. According to statistics, up to the first 10 days of January the reserve of usable water in the Guanting and Miyun reservoirs amounted to 314 million cubic meters, which is only 40 percent of the reserve during the same period last year. Since the beginning of winter, the underground water level has not yet returned but has continued to drop. The underground water level in the mountain regions has dropped 4 to 5 meters compared to the same period last year. The underground water level in hilly regions and semimountainous regions has dropped 3 to 4 meters. Of the 37,000 mechanized wells for farming in the Beijing suburbs, only 12,900 wells can draw water normally. There are 14,500 wells that can produce only half the normal output. There are 9,700 wells that either can only be drawn intermittently or have dried up.

The serious drought has already continued for more than 2 years since the summer of 1979. In 1981 there was less rainfall in the city. Floods did not occur during the flooding period, and the amount of water in the two large reservoirs at one point had dropped to below the dead reserve level To guarantee the needs of city life and industrial production, the two large reservoirs have had to stop supplying water to the agricultural sector in the Beijing suburbs ever since the first 10 days of June of last year (not including the suburban vegetable fields and the dislocated residents in the area of the Miyun Reservoir). In August, the State Council held an emergency meeting on the use of water in the Beijing and Tianjin areas. It was decided that the Miyun Reservoir would not supply any more water to

Tianjin. Later, the city committee and the city government held two citywide mass meetings on conserving water. For several months now, all businesses throughout the city have been conscientiously implementing the spirit of the directives of the State Council and the city. A lot of work has been done in adhering to the directives to lessen the use of water and to exert efforts to conserve the use of water. Visible results have been attained. But the leadership of some units and the masses lack an understanding of the urgency and the importance of conserving the use of water, and their measures have not been sufficient. The city's water conservancy department has called upon all fronts in the city to follow the demands and plans of the city committee and the city government. The directives on the use of water issued by the city have been strictly and scientifically calculated. As long as they are fully implemented, the only water sources in the whole city at present will barely be able to supply enough water until the end of this June, just before the arrival of the rainy season. Recently, the city had two light snowfalls; the amount of precipitation in most areas of the city was only 2 or 3 millimeters. The western mountain region basically have not had any snow. Concerned departments believe the broad masses must not entertain any wishful thinking, but must start out from the belief that the drought will continue, so that they will prepare for a long period of conserving water and fighting drought. The farm villages in suburban Beijing must continue to utilize the presently available mechanized wells and the basic amount of flow in the river channels to manage winter irrigation well, to repair leaky canals and waterways, and to level the land. Mechanized wells must be repaired, and technical training of operators and electricians must be carried out well in order to improve the effectiveness of irrigation. In irrigation, the production responsibility system must be implemented. Rational quotas must be established. Wards and counties concerned must face reality and be determined to reduce the area planted in paddy rice this year. Businesses and residents in the city must also act and make additional contributions to water conservation.

FOOD GRAIN PRODUCTION MUST NOT BE SLIGHTED

Beijing ZHONGGUO NONGMIN BAO in Chinese 31 Jan 82 p 1

[Commentary: "Never Slacken Food Grain Production"]

[Text] "Never slacken food grain production; actively develop diversification" is a party policy which must be implemented with determination and implemented on an overall basis. According to the reactions of many readers, some localities lack the overall picture when they implement this policy. They have overly reduced the slowing area for food grains and have used additional manpower and materials to develop economic crops and diversification. As a result, food grain production is affected. This is wrong.

Our nation has a population of 1 billion. Feeding them is still a major task. At present, our nation's amount of food grains per capita is still not large. There is still a shortage in the supply of food grains. This situation should attract the serious attention of the localities and should not be neglected.

Economic crops should be developed in a big way. But we should rely mainly on [measures] that have not been utilized, such as increasing the unit yield, improving quality, and utilizing unclaimed mountains and unclaimed beachland. We must not rely on continued reduction of the area sowed in food grains. Of course, local and small adjustments are still allowed; especially, our nation's northern region still must continue to expand the areas of cotton and sugar crops. But generally speaking, the ratio of economic crops and the sowing area of food grains should be stabilized at the present level so that production of food grains can develop steadily. We should see the mutual benefits of diversification and food grain production, but we should also see the mutual limitations. In our nation, if food grain production does not continue to develop, if we rely on reducing the area sowed in food grains to develop economic crops, the results will be that economic crops will not be able to develop very well.

Comrade Chen Yun [7115 0061] recently pointed out with emphasis that the agricultural economy is an important part of the national economy. In agricultural economy, economic planning should be the main effort and market regulation should be a supplementary effort. After the responsibility system of linking production and contracting work has been implemented, the emphasis should still be on doing things according to national plans. Cadres and masses of commune members in our broad number of farm villages should consider the overall situation, recognize the whole, and think of the benefits to the state. If we consider only the benefits that are before our eyes, if we select only the methods that benefit ourselves, if we plant only that which brings us large benefits, do only that which earns us a lot of money, and develop blindly and freely, the result will be the destruction of the national plan. This will not benefit the construction of socialism, and it does not coincide with the long-range benefits of the farmers. Only policies that benefit both the farmers and the nation are correct and good. Only by arranging production in this way can agriculture realize overall development.

The best part of the year is the spring. Now is the time to establish and implement this year's production plans. We must implement the policies of the Central Committee on an overall basis. We should actively develop diversification and the family sidelines of commune members, but we must never slacken food grain production.

BRIEFS

ANIMAL FEED CONFERENCE--Beijing, 26 Apr (XINHUA)--The Ministry of Commerce held a national animal feed work conference in Beijing from 16 to 26 April. The conference called for efforts to produce a greater variety of nutritious mixed feed to facilitate the development of animal husbandry and fishery. It has been demonstrated that some 60 to 100 jin of grain can be saved per pig if it is fed scientifically prepared mixed feed when the animal grows to about 170-180 jin. Besides, the feeding period can be reduced by 2-3 months and the cost can be lowered by some 20 percent. The conference called for increasing the national annual feed output from 1.5 million dun in 1981 to 6-7 million dun by 1985 when mixed feed should account for more than 30 percent of the total amount of feed produced. PLANTING NEW VARIETY OF PADDY RICE GAINS RESULTS

Beijing GUANGMING RIBAO in Chinese 7 Feb 82 p 1

[Article by Bai Jingzhao [4101 0079 0340] and Li Hanrong [2621 3352 2837]: "By Reforming the Sugarcane Planting System and by Planting a New Variety of Paddy Rice, Fujian Agricultural Academy Actively Popularizes Scientific Research Results and Realizes Happy Achievements"]

[Text] Last year, the Fujian Agricultural Academy popularized a new planting system and a new variety of paddy rice--"233"--over large areas to improve the utilization of the energy from light on sugarcane plantations. The efforts have produced widespread increased yields on 25,000 mu of sugarcane and 300,000 mu of paddy rice.

Xianyou County in Fugian Province is an important sugarcane-producing region of our nation. In the past, the forecrop of sugarcane was always completely wheat. About 20 days prior to harvesting the wheat, sugarcane was companion-planted between the rows of wheat. This method of cultivation caused sugarcane plants to grow slowly and the germination rate to be low, because the sugarcane was planted too late and because the sugarcane plants were in the shadow of the wheat plants. In recent years, this academy's sugarcane expert, Prof Zhou Keyong [0719 0668 8673], led the Sugarcane General Research Institute in conducting a study of [how to] reform the planting system in sugarcane regions. After the experiment, visible results were realized. This new planting and cultivation system will change the forecrop of sugarcane from wheat to part wheat and part vegetables, interplanted equal distances apart. The low utilization rate has been improved by regulating and improving the permeation of light in the various periods between the sugarcane and the interplanted and companion-planted crops, with the result that the sugarcane's germination rate has been improved and growth has been hastened. They quickly joined Xianyou County to develop popularization together. The year before last, they popularized [the method on] 10,000 mu. Last year, that academy carried out three reform measures in Xianyou County and popularized the method over 25,000 mu.

The Department of Agriculture at the academy has selectively bred via hybridization and cultivation a new early xian variety, "233." Last year it was widely popularized throughout the province. They signed a contract with the provincial science committee and guaranteed a 10-percent increase in yield over an area of 100,000 mu. The results of planting at each locality produced an average increase of 10 percent over the current dominant variety; many localities produced a yield of 1,000 jin per mu in one cropping season. Dongqiao commune in Putian planted the early crop over 380 mu. The average yield showed an increase of 23 percent over the dominant variety, and a per mu yield surpassing 1,000 jin was produced on 300 mu.

FIRST SECRETARY MEETS FERTILIZER EXPERTS

OW302154 Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 29 Apr 82

[Text] The international academic forum on nitrogenous fertilizers concluded in Fuzhou on the afternoon of 29 April. The closing ceremony was presided over by Dr Greenland, deputy director of the International Rice Research Institute. Dr Stangel, deputy director of the International Fertilizers Development Center, gave a brief report at the forum. (Gao Huilin), director of the soil fertilizer institute under the Chinese Academy of Agricultural Sciences; (Chen Huakui), chairman of the China Soil Fertilizer Society and president of the Central China College of Agricultural Sciences; and Mr (Kin), director of the Burmese Institute of Agricultural Sciences, spoke at the forum.

Twenty-six Chinese and foreign experts presented academic reports and held panel discussions during the 4-day session. Lively discussions were held by the experts and scholars on opening up new sources of and effectively using nitrogenous fertilizers. It was maintained that the forum promoted scientific and technological cooperation and friendship among the various countries.

During the forum, the representatives visited the Fujian College of Agricultural Sciences. They had a high opinion of the college's achievements and expressed keen interest in the college's research of chemical fertilizers, topdressing machinery and cycling of organic matter.

The Fujian College of Agricultural Sciences exchanged souvenirs with the International Fertilizers Development Center and the International Rice Research Institute at the closing ceremony.

Xiang Nan, first secretary of the Fujian Provincial CCP Committee, called on some of the experts, scholars and officials of some international research organizations on 29 April. Beginning 30 April, the experts and representatives will tour Wuyi Mountain in Jianyang County. Some representatives will stay to attend training classes beginning 4 May.

CSO: 4007/396

BRIEFS

FERTILIZING METHOD--An advanced experience of applying chemical fertilizers deep into soil is being popularized in Fujian Province. The new application method can raise the utilization rate of chemical fertilizers by 20 to 30 percent and increase per mu grain output by 86 jin. In 1981 about 500,000 mu of land in Fujian was fertilized by using the deep application method. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 27 Apr 82 OW]

MARINE CULTIVATION--In 1980 and 1981, Fujian Province expanded the area of marine cultivation by 46,000 mu and increased the output of marine products by 109,000 dan. In the province, there are 2 million mu of coastal shallow water area suitable for marine cultivation. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 29 Apr 82 OW]

CSO: 4007/396

BRIEFS

FLOOD PREVENTION CONFERENCE--According to weather forecasts, rainfall in the upper reaches of the Huang He in Gansu will be comparatively abundant this year. The Gansu provincial forum on flood prevention and reservoir safety, which concluded on 27 April called for continued efforts to strengthen dike and reservoir management and prepare against floods. [SK292217 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 28 Apr 82 SK]

SHEEP-RAISING ACHIEVEMENTS--Since the 3d Plenary Session of the 11th CCP Central Committee, Yongchang County, Gansu Province, has scored remarkable achievements in raising sheep. By the end of March, the county had over 283,600 head of sheep, surpassing the figure of the corresponding 1978 period by 34 percent. Each agricultural household has 608 head of sheep. BRIEFS

CANE SUGAR PRODUCTION--The 1981-1982 sugar refining season in Guangdong Province has basically concluded. The province's output of cane sugar has reached 1.285 million tons, 26.8 percent more than in the preceding sugar refining season. The province reaped a big bumper sugarcane harvest last year. The amount of sugarcane which all communes and brigades in the sugarcane production areas and state-run farms supplied to the sugar refineries reached 11.65 million tons, 38 percent more than in the preceding sugar refining season. [Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 20 Apr 82 HK]

RICE RESEARCH CENTER--After approximately 3 years' design and construction, the Guangdong Provincial Paddy Rice Research Center which the Ministry of Agriculture has invested in and built has been recently and basically completed. The Ministry of Agriculture has decided that the inauguration ceremony for this research center will be held at the end of May. This paddy rice research center is situated in the Guangdong Provincial Agricultural Science Institute in Shipai, Guangzhou. After the national conference on science, to speed up the modernization of agricultural science and technology in our country, the Ministry of Agriculture has invested in seven research centers, of which the provincial paddy rice research center is one. The total in this research center amount of investment is 3.67 million yuan and its total construction area is some 97 million square meters. Some of its main apparatus and equipment have been imported from abroad. This research institute will be managed and used by the paddy rice department of the Guangdong Provincial Agricultural Science Institute. [HK161257 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 13 Apr 82 HK]

HAINAN SEAWATER BREEDING--After friendly consultation, the Hainan Li-Miao Autonomous Prefectural International Trust and Investment Company recently signed a contract with the (Toko) Company, Japan, on developing the seawater breeding trade in the form of cooperative production. They also established the Hainan Autonomous Prefectural Seawater Breeding Development Company. According to the provisions of the contract, the (Toko) Company will invest 100 million yen in the Hainan Autonomous Prefectural Seawater Breeding Development Company and be responsible for technical guidance while Hainan Autonomous Prefecture will provide the place for seawater breeding. The period of cooperation will be 15 years. Hainan Autonomous Prefecture will get 25 percent and the (Toko) Company will get 75 percent of the net profits. BRIEFS

TOBACCO PRODUCTION MEETING--From 20 to 23 April, the Guizhou Provincial People's Government held a meeting in Qianxi County on flue-cured tobacco production. The meeting made specific arrangements for flue-cured tobacco production in this province this year. Attending were 187 leaders from all prefectures, autonomous prefectures, municipalities and counties, responsible persons of relevant departments and scientific and technological works. Shen Yunpu, vice governor, spoke on this year's flue-cured tobacco planned production. The meeting conveyed the spirit of the instruction of the central authorities on strictly arranging for flue-cured tobacco production in accordance with the state plan and examined the situation of carrying out the plan for cultivating flue-cured tobacco in the province this year. It was discovered that some prefectures had not arranged for flue-cured tobacco production in accordance with the state plan and had expanded areas for cultivating flue-cured tobacco. The meeting held that this province is now still not self-sufficient in grain and if we blindly expand areas used for cultivating flue-cured tobacco, it will surely reduce the areas that can be used for cultivating grain. In accordance with our state capacity for cigarette production, we are not allowed to expand areas for cultivating flue-cured tobacco in a blind and unrestricted way. The meeting demanded that poltical and ideological education be conducted for peasants engaged in growing tobacco. [HK031455 Guiyang Guizhou Provincial Service in Mandarin 2315 GMT 25 Apr 82 HK]

BAODING PREFECTURE'S MEASURES FOR RURAL WORK

HK290725 Shijiazhuang HEBEI RIBAO in Chinese 21 Apr 82 p 1

[Report: "Baoding Prefectural CCP Committee Formulates Ten Measures for Strengthening Rural Grassroots Work"]

[Text] While conveying the documents of the national rural work conference, the Baoding Prefectural CCP Committee leaders have personally gone deep into reality to investigate and study how to strengthen rural grassroots work, and have accordingly formulated the "Baoding Prefectural CCP Committee's 10 measures for strengthening rural grassroots work." The text of this document follows:

Since the third plenary session, the grassroots rural organizations in Baoding Prefecture have done a lot of work in actively implementing the party's line, principles and policies, readjusting and restructuring the agricultural economy, setting up and perfecting the agricultural production responsibility systems and building spiritual civilization. Excellent and great changes have taken place in the rural situation. The grassroots cadres have worked hard, made great and arduous efforts, and scored outstanding successes. Such an excellent rural situation, rarely seen before, could not have been accomplished without their hard work. However, in the current new period of historical development, it has been revealed that our rural grassroots work is far from meeting the needs of the great developments and changes in the situation. Certain grassroots leadership groups are lax and weak and their political and ideological work is poor. Certain grassroots cadres lack sufficient understanding and grasp of the party's line, principles and policies, and are not bold enough in work. A very small number of cadres are listless, display bad work style, damage the collectives, pursue private interests, get entangled in factional interests and cause disunity, with the result that leadership groups are paralyzed or semi-paralyzed. These things show that there has to be a process of matching and understanding the new problems in the new situation. They also show that our commune, county and prefectural leading organs have not done enough study of grassroots work or made enough effort to get down to the grassroots and help solve the practical problems there. Unless we take effective action to rapidly change this situation, it will be impossible to implement well the party's correct principles and policies, the measures for building socialist agriculture will turn into empty talk, and the vital interests of the masses will be harmed and their socialist enthusiasm damaged. All this will cause a passive situation in work, which will affect the development of the excellent situation. Hence, the party committees at all levels, especially of the counties and communes, must be resolved to devote great effort to strengthening grassroots work, rectify the grassroots organizations, implement the spirit of the "minutes of the national rural work conference" circulated by the CCP Central Committee, fully mobilize the enthusiasm of the grassroots cadres, and enliven rural work. We must, therefore, resolutely adopt the following measures:

1. We must clearly understand that current rural work is guided by the "minutes of the national rural work conference" and put the stress on strengthening the leadership of the grassroots organizations, upholding the path of socialist collectivization, and perfecting the production responsibility systems. The county and commune party committees must carry out a universal investigation of the grassroots party branches and the brigade management committees to find out their situation, put forward specific ways of strengthening the grassroots organizations, rapidly rectify paralyzed and semi-paralyzed organizations, help weak and powerless organizations, and consolidate and raise the standards of the progressive organizations. In connection with clearing out the "people of three categories," we should enable every grassroots organization to become a core and a powerful fighting force uniting the masses to forge ahead, seriously carrying out the party's line, principles and policies and doing a good job in building socialist material and spiritual civilization. A new situation will thus emerge in grassroots work.

2. Every county must set up a special rural grassroots work team. The main tasks of the team are: 1) to rectify the grassroots leadership groups; 2) to perfect the production responsibility systems and take stock of financial affairs; 3) to help the grassroots to solve some longstanding, great and difficult problems. A deputy secretary of the county CCP Committee should be responsible for this team, which should be composed of 30 to 50 cadres, chosen from the county and communes, who have a definite grasp of policies, good work style, strong sense of responsibility, ability and drive. Functions, rules and regulations should be drawn up for them after a short training period. Under the direct leadership of the county CCP committee, the team is to assist the commune party committees and help to solve problems on backward brigades with many problems.

3. Strengthen the commune party committees and management committees. Every county should transfer from the county organs a number of outstanding young and strong cadres with good thinking and work style, drive, ability and specialized knowledge and send them, especially young ones, to work on the communes; some of them should fill the posts of Nos 1, 2 and 3 men on the communes. In view of the fact that the current main sources of cadres are graduates of universities and secondary technical schools and ex-army cadres,

we should stress that all county section and bureau chiefs who have not done grassroots work must be sent down to the communes to be steeled by holding grassroots posts. Leading commune cadres whose work is outstanding can join the leadership groups of the county party committees and government.

4. Actively popularize the experiences of county and commune cadres in Boye County in going to stay and work on the brigades and production teams while retaining their posts and salaries. We should vigorously support cadres who volunteer to go down to work in the grassroots. They can be sent down to stay at units of their choice and their tasks and the duration of their stay in the grassroots (it can be 1, 2 or 3 years) must be clearly defined. They should be examined at the completion of their term, and those who have done very well should be commended. Their success should also be made a promotion criterion.

5. Boldly select and promote outstanding young grassroots cadres. In view of the present low number of young party members in the rural party branches, it is particularly necessary to pay attention to strengthening the brigade management committees. We should boldly select and promote to these committees outstanding non-party member cadres who have come to the fore since the third plenary session and ensure that they genuinely undertake political and economic duties. After active cultivation and steeling, we should prepare to replenish the party committees with new blood by actively cultivating and steeling these people.

6. Strengthen rural ideological and political work. The grassroots party branches must put education for the peasants in ideology, politics and policies in the primary position. It is necessary to put the party lesson and life systems on a sound basis, rectify party discipline, bring into play the model and leading role of party members, and actively popularize systems for examining and assessing party members and for having party members keep in touch with the masses by being responsible for households. We must bring into play the role of the CYL, Federation of Women, and militia organization. We should undertake the building of civilized villages by carrying out education of various types for the peasants in "upholding one thing," "keeping two things unchanged," "taking simultaneous account of the interests of three things," and the "four prohibitions," and in observing the planned parenthood regulations.

7. Carry out universal training of grassroots party members and rotational training of commune and brigade cadres. This is to be done in a planned way. Every county CCP Committee must draw up a specific plan. We must make use of the slack agricultural season, during which the communes should adopt various methods such as collecting everyone together for lessons, holding individual group discussions and so on to conduct education for the party members in the nature, work style, discipline, and current policies of the party. For the cadres, the main thing is to seriously study the "minutes of the national rural work conference" circulated by the CCP Central Committee,

and truly master this document. The county party committees should continually study the party's principles and policies in close connection with reality and exchange experiences in grassroots work by summing up experiences and carrying out rotational training of commune cadres. The prefectural and county CCP committee party schools should carry out planned training of the principal leading commune and brigade cadres; they should study Marxist-Leninist philosophy and economic theory and continually enhance their level of ideology and policy and their work ability.

8. The county CCP committees should organize temporary rural work groups in light of the needs of rural work; under the leadership of county-level leading cadres, they should go down to the grassroots to carry out inspection, supervision, investigation and study. They must go right down to stay at selected basic units and help the grassroots to solve practical problems. At present the effort should be concentrated on halting the three sinister trends of forcibly occupying land for building houses, indiscriminate tree-felling, and sharing out collective property. The method is to combine the teaching of party members and cadres to take the lead with the handling of individual cases of violations of law. It is also necessary to help the grassroots to solve certain longstanding, great and difficult problems. We must vigorously support cadres who are just in their dealings and bold in handling problems.

9. It is necessary to gradually set up commune police stations in order to preserve social order in the rural areas, protect the collective economy and promptly deal with criminal cases. The number of personnel assigned to these stations depends on the size of the commune (the establishment question is to be solved among the public security ranks). Under the leadership of the county public security bureaus and commune party committees, these stations are to strengthen public order work in the rural areas and bring into play the role of grassroots security and civil mediation organizations.

10. Seriously implement the remuneration for grassroots cadres. The county CCP committees are to lay down clear stipulations according to the circumstances for the limits of grassroot cadre remuneration. The communes must clearly stipulate the number of brigade and production team cadres who can receive subsidies and the methods of paying them, bases on the spirit of better troops and simpler administration. It is necessary to stipulate work tasks, rules and regulations for the grassroots cadres, establish job responsibility systems, and lay down measures for handing out rewards and penalties.

YANG YICHEN WATCHES PLANTERS' TRIAL OPERATION

SK300515 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT
29 Apr 82

[Excerpts] According to our reporter (Liu Baiying), there is good news for peasants who grow food grains other than wheat and rice. After many years of research, corn precision seed planters and hand-guided intertilling planters have been successfully trial-produced. They were proved to be very efficient at a recent trial operation in the (Xingfu) commune of Shuangcheng County.

The result of the scientific research on the corn precision seed planter has filled in a blank in our province's corn precision dibbling and indicates that our province's agricultural mechanization has reached a new level. Corn fields in our province cover a relatively large area, accounting for approximately one-third of the province's grain acreage. Making a breakthrough in mechanized corn sowing and precision dibbling is an urgent issue which needs to be solved and has been studied by agricultural scientific research departments for a long time.

After an appraisal at the trial operation, experts held that the hand-guided intertilling planter is a relatively ideal and very applicable small farm machine in our province's rural areas. It meets the need of the rural areas after various responsibility systems have been established.

Simple in structure, small in size and highly efficient, the hand-guided intertilling planter can sow 25 mu of farmlands per hour at a cost of 2 jiao. It is very popular among the peasants. Not long ago, 700 such planters were sold out as soon as manufacturers put them on the market.

Leading comrades of the provincial CCP committee and the provincial people's government including Yang Yichen and Wang Luming recently went to the (Xingfu) commune of Shuangcheng County to watch the demonstration of mechanized sowing in corn fields. They spoke highly of the success in trial producing the corn precision seed planters and hand-guided intertilling planters.

HEGANG CITY FOOD PROCESSING INDUSTRY GAINS NEW GROUND

Grain, Oil Management Combined

Harbin HEILONGJIANG RIBAO in Chinese 12 Jan 82 p 1

[Article by Communications Group of the Provincial Grain Bureau: "Being the First To Turn Losses Into Profits in Managing Food Grains in the Province, Hegang Has Created New Path in Processing Oils and Food Grains; Last Year It Made a Profit of 1.02 Million Yuan, Following Profit of 570,000 Yuan the Year Before Last"]

[Text] The Hegang Municipal Food Grain Department has broken away from the old limitations of separate management of food grains and edible oils. It has combined the management of food grains and oil with the development of food processing and actively launched diversification. This has provided convenience in the life of the masses and also has turned around many years of business losses. In 1980, a profit of 570,000 yuan was made. In 1981, profits reached 1.02 million yuan; [thus,] this became the first food grain department in the province to make a profit 2 years in a row.

This city's food grain department had suffered losses for many years. In 1976, losses reached 12.52 million yuan, an increase of 11 times the 1966 figure. Following the Third Plenary Session of the 11th Chinese Communist Party Central Committee, the broad number of workers carried out a conscientious analysis and study and believed that managing one single commodity and managing it poorly were the important reasons for such losses. They liberated their thinking and lifted self-imposed restrictions to develop diversification. They conscientiously managed three links.

They developed diversification and improved economic results. They reformed technology, improved the percentage of finished products, and reduced the processing cost of food grains and edible oils. At the same time, they paid special attention to the comprehensive utilization of sideline products. They used corn embryo and corn embryo cakes to press edible oil. They used soybean dregs to manufacture soybean protein powder. They extracted such products as phosphatides from oil dregs and organized exports so that they became an important source for increasing income.

They developed food production and increased the profits of food grain shops. In the past, food grain shops throughout the city sold only uncooked food grains and oil and did not sell cooked foods. Now, they use simple methods and the method of "snowballing." The city's food grain bureau subsidizes a little money and materials to enable the shops to add simple equipment and to build simple shacks and tents next to the shops. Food processing facilities behind the shops have been set up by 54 different food grain shops, and 7 small noodle plants and food service departments have been set up at 12 mines and mine pits to process and sell beans and soup, oil sticks, muffins, baked muffins, sweet bean dumplings, bean curd pudding, and sweet dumplings for the Lantern Festival--a total of more than 10 varieties of foods to supply the market. Many foods have been sold by the food grain stores and also at kiosks in the marketplace. Some 120 trucks are driven through the streets to various places and factories. At present, the food grain stores of this city have become general food stores. Eight food grain stores that negotiate price sales have been set up throughout the city. Shelled peanuts, rice, sesame, mung beans, and polished glutinous rice have been brought in from other provinces to supplement the different needs of the residents. Last year's profit on food grain sales and the profit on negotiated prices throughout the city in 1980 increased 6.9 percent and 11.8 percent, respectively.

Develop the potential in conservation; reduce storage losses. In recent years, the city's Food Grain Bureau have been storing food grains at docks and storing food grains in loose form in warehouses, utilizing temperature differences between the seasons to enlarge warehousing capacity. At the same time, mechanized operations are being utilizied. The backward method of the past of manually transporting food grains has been changed. Unprocessed food grains are loaded, unloaded, transported and stored in "four loose forms," thus reducing packaging equipment. They also have carried out important measures to inspect the weight and quality of warehoused food grains, dried damp food grain, and rationed and paid for food grains directly according to the changes in season. Intermediate steps have been reduced, and costs have been lowered.

Commentary Calls for Emulation

Harbin HEILONGJIANG RIBAO in Chinese 12 Jan 82 p 1

[Commentary: "Travel the Path of Processing Edible Oils and Foodstuffs"]

[Text] The Hegang Municipal Food Grain Department has lifted its spirit, liberated its thinking, broken away from the narrow path of the past of solely managing food grain and edible oils, and created a new road to engage in food processing for food grains and edible oils. This has improved food supplies in the market and provided convenience for the people, and it has also turned business losses around and created the province's first food grain management business covering a large area without suffering losses. Their experience is very important and precious and is worth studying conscientiously by the food grain departments of all localities.

What is the task of the food grain department? Of course, it should be to manage well the procurement, storage, and supply of agricultural products such as food grains. In the past, the food grain department had always done this. Considering objective needs, however, just doing this has long become insufficient. As the standard of living of the people gradually rises, the broad masses are urgently demanding that more food and inexpensive food be supplied to them. To reduce the burden of house chores so that more time can be found for working and learning, they also need to obtain a richer supply of foods in the market. This requires the food grain department to follow the road of food and edible oil processing on the basis of managing the supply of food grains and edible oils well and to join the foodstuffs industry departments and commerce departments in further developing the food processing industry. As for the food grain department itself, this is a fundamental way to turn management losses around and reduce the state's financial burden. Via industrial processing, food grains and other agricultural byproducts can be converted into sugar and wine and oil and starch and nutritious foods, health foods, medicinal foods, etc. This does not mean changing the material forms of food grains and other agricultural byproducts for the convenience of the people to consume but means fully extracting and rationally utilizing the nutritious contents of edible raw materials. In this sense, food processing itself increases and conserves social wealth. The better the food grain department does this job, the more social wealth will be created and conserved, and profits will necessarily increase. In this way, the dead "chip" of losses in managing food grains will be brought to life. Buy more, sell more, and lose more will be changed to buy more, sell more, and profit more.

Now, many of our province's food grain departments have gradually emphasized the processing of food grains and edible oils and have established "shop fronts with food factories in the back" on a widespread basis. Food shops that concurrently engage in food processing are welcome, but this type of processing is mostly at a low level because of lack of familiarity in acquiring skills. The road is still very narrow, and even such simple processing has not yet been established in some localities. This shows that some comrades still lack an understanding of the important significance of food processing. The leading comrades of the food grain departments in each locality should begin by increasing understanding, planning well, and gradually developing the food processing industry for food grains and edible oils as the direction for future development. They should also learn advanced domestic and foreign experiences, strengthen scientific research in the foodstuffs industry, and continue to open up new fields in the processing of food grains and edible oils so that processing techniques can gradually develop a higher level. The processing of food grains and edible oils is something that benefits the people and society greatly. Each profession and business should pay attention and should help the food grain department by providing capital, materials, locations, and techniques so that it will be able to do this well. At the same time, attention must be paid to strictly implement price policies and to use "industry to supplement commerce, use negotiated prices to make up for lower prices, use imports to nurture local products, and use profits to make up for deficits," within the confines established by policy. Equalizing prices and increasing prices at will should never be allowed.

Our province is an important agricultural base for the nation. It has especially superior conditions for developing an industry to process food grains and edible oils. We should have more confidence in promoting our province's food processing industry to process food grains and edible oils and to realize new achievements in enlivening the market, improving the people's life, and turning around losses in food grain management and sales.

BRIEFS

FOREST INSECT PESTS--Since the beginning of April, some forest areas in Heilongjiang Province, including Yichun, Mudanjiang, Hejiang and Songhuajiang forest areas, have been plagued by insect pests covering some 400,000 mu. Department concerned disclosed that the plague situation is worsening and urged all localities to give accurate forecasts and information on insect pests and devise plans to control them. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 28 Apr 82 SK]

MAY TEMPERATURES--According to the central and Heilongjiang provincial meteorological departments, temperatures in May in the province are normal, and may rise slightly higher than usual. Rainfall will increase 10 to 20 percent in Nenjiang and Heihe prefectures. Other localities will receive 10-20 percent less rainfall than the previous year. Rainfall will be concentrated in middle and late May. The favorable temperature conditions are conducive to field crop cultivation. A drought in the southwestern part of the province will possibly occur. [SK012214 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 30 Apr 82 SK]

BEET SOWING OPERATION--By the end of April, Suiling County, Heilongjiang Province, had sowed 63,000 mu of beet crop, overfulfilling its sowing plan by 3,000 mu. The county's beet sowing plan for this year is 90,000 mu which will be cultivated by collectives and it has also assigned its commune members to sow 60,000 mu of beets on their private plots or fodder fields. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 1 May 82 SK]

AFFORESTATION PROJECTS--Songhuajiang Prefecture, Heilongjiang Province, as of 27 April had planted 500,000 mu of trees and overfulfilled its spring afforestation plan and surpassed the figure of the corresponding 1981 period by 39 percent. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 27 Apr 82 SK]

'XINHUA' URGES GREATER ATTENTION TO RURAL MARKETS

OW260353 Beijing XINHUA Domestic Service in Chinese 0014 GMT 25 Apr 82

[XINHUA correspondent's commentary: "It Is Necessary To Attach Importance to and Study Rural Markets"]

[Text] Changsha, 25 Apr (XINHUA)--The Ministry of Light Industry recently held a national fair in Changsha on light industrial goods for rural areas. During the brief 7-day session, over 83,000 purchasing contracts were signed between light industrial enterprises and representatives of rural supply and marketing cooperatives from various parts of the country; total turnover exceeded 1 billion yuan. The brisk purchasing and marketing activities at the fair show that there is a huge market in the countryside. Therefore, production departments of daily consumer goods must attach importance to and study rural markets and strive to turn out goods that meet the demands of rural markets.

Only some 5,000 representatives of rural supply and marketing cooperatives were invited to the fair, but total attendance exceeded 30,000. How can a fair attract so many comrades from rural supply and marketing cooperatives? The answer is that peasants are urgently in need of daily consumer goods. Many representatives of supply and marketing cooperatives reflected that since the peasants' living standards have greatly improved in recent years, supply and marketing cooperatives are having difficulties supplying peasants with sufficient commodities. For this reason, the representatives brought with them long ordering lists and huge sums of money. At the fair, it was surprising to find that trade talks were so active, transactions concluded so quickly and turnover so big. Many nonbrand name products selling slowly in some localities became quick selling items at the fair. Orders for the Kunpeng-brand bicycle produced in Hunan Province--which has a market plan of only 50,000 bicycles--reached 500,000 during the first 2 days of the fair.

The brisk sales at the fair deeply impressed the comrades of the light industrial departments. They said: One of the important factors for the current stockpiling and sluggish sales of some daily consumer goods in some localities is the lack of attention being given to opening up the huge rural market; other factors are that variety and design of some commodities do not meet market demand and that commercial channels are obstructed. In some localities, daily consumer goods production departments tend to attach undue emphasis on cities and overlook the countryside with regard to production arrangement, material distribution and product design. Consequently, they pay more attention to the needs of cities and less to the countryside, and product variety and design tend to fall in with the tastes of urban consumers rather than the needs of peasants.

Also, we can see that among the daily consumer goods on display, some are unsuitable for marketing in the rural areas. For instance, pure cotton textiles needed by the peasants are scarce. The style and design of garments are too outlandish. Most of the leather and plastic shoes are too small, slender and high-heeled, contrary to the needs of peasants who require larger-sized, medium- or low-heeled shoes with broad soles. Moreover, plastic goods, cooking utensils, ceramicware, furniture and small daily commodities are more suitable for use by small families in cities rather than for families in the countryside. This shows that the daily consumer goods production departments are unfamiliar with peasants. They are short of study on the peasants' consumption pattern, mentality and spending habits and lack understanding of the changes in rural market needs.

Ours is a country with a peasant population of 800 million. The peasants have more and more money at their disposal since the implementation of the production responsibility system in the rural areas. If the production and supply of daily consumer goods fail to meet their needs, currency recovery, the stability of commodity prices, the worker-peasant alliance and social stability and unity would be adversely affected. For this reason, the development of daily consumer goods needed by the countryside is not solely a matter that concerns production and the economy but is also an important event having a bearing on the overall situation.

To enable daily consumer goods to freely enter rural markets, it is presently necessary to vigorously broaden the channels for product circulation in the rural areas; in addition, industrial enterprises must set up organizations to collect rural market information, organize product designers to come up with new products catering to peasant needs, deliver products to rural areas for trial marketing and sales exhibitions and canvass the peasants' opinions.

Many comrades of the rural supply and marketing cooperatives who attended the fair have reflected that currently there are still many problems with regard to the supply of daily consumer goods to rural areas. First, the quantity of consumer goods shipped to rural areas is insufficient. Product variety, design and specifications are incomplete. Peasants have almost no access to hot items--particularly bicycles, sewing machines and low-priced wristwatches--because they are often retained at various levels and sold by favoritism. Second, there are too many links obstructing the free circulation of products. Third, some localities and departments impose barriers and arbitrarily block commodity circulation. These problems must be seriously studied and resolved.

Commercial departments must attach importance to and study rural markets. They must earnestly adhere to the principle of "giving priority to cities in the supply of agricultural and sideline products and giving priority to the countryside in the supply of daily industrial goods." They must appropriately expand the proportion of daily consumer goods sold in the countryside and economically support the operation of rural supply and marketing cooperatives in implementing various policies. A new situation will soon emerge in the production and supply of daily consumer goods to the countryside as long as we pay attention to and closely cooperate with the various departments.

SPRING FARMING--More than 2.8 million peasants in Jilin Province have plunged into spring farming every day. As of 20 April, the province planted 9.32 million mu of various crops, an increase of 1.62 million over the corresponding 1981 period, and grew 240,000 mu of paddy seedlings, an increase of 40,000 mu. [SK211015 Changchun Jilin Provincial Service in Mandarin 2200 GMT 20 Apr 82 SK]

ARTIFICIAL RAIN--The Jilin Provincial Civil Aviation Bureau dispatched airplanes to make artificial rain in Nongan, Huaide, Changling and Yongji counties on 28 April. The artificial rain would help ease the drought in these counties. [SK292214 Changchun Jilin Provincial Service in Mandarin 2200 GMT 28 Apr 82 SK]

WEATHER FORECAST--The Jilin provincial weather station forecast on 24 April that, affected by low pressure in the Mongolian area, Jilin Province will experience high temperatures before 26 April. The highest temperature will be 25-27 degrees centigrade. Baicheng Prefecture may reach 28-30 degrees centigrade. Plains areas will experience 7-8 grade southwesterly wind. Beginning 26 April, cold spells will hit Jilin Province and cause temperatures to drop. Most areas will experience rainfall and 6-7 grade gales. The weather station urged all peasants to strengthen seedbed management because now is the time for cultivating paddy rice seedlings. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 24 Apr 82 SK]

SOYBEAN SOWING--Yushu County, a soybean base in Jilin Province, plans to expand 3,000 mu of farmland to grow soybeans this year. By 21 April, the county had sowed 270,000 mu of the soybean crop. [SK292238 Changchun Jilin Provincial Service in Mandarin 1100 GMT 27 Apr 82 SK]

TREE PLANTING--Jilin Province achieved remarkable results in spring afforestation. As of 16 April, the province had afforested 1.01 million mu of land and grew 119,000 mu of saplings. Various cities and towns across the province planted 13.27 million trees on a voluntary basis, and rural areas planted 27.4 million trees. According to statistics compiled from early April to 16 April, some 8.79 million people in urban and rural areas participated in tree-planting activities. However, the development of afforestation work is uneven in the province. Supplies of big stocks fall short of demands. [SK232222 Changchun Jilin Provincial Service in Mandarin 1100 GMT 22 Apr 82 SK]

SPRING SOWING--Yushu County in Jilin Province has adopted three measures to fully utilize farm machines in spring farming. The county is dispatching some 2,000 tractors daily and has so far had 2.56 million mu sown to field crops, 70 percent of the field crops acreage. BRIEFS

CHAOYANG SPRING SOWING--Drought-ridden Chaoyang Prefecture in Liaoning Province has lost no time in sowing while there is sufficient moisture in the soil after rainfall on 27 April. From 27 to 30 April, the prefecture crash sowed 700,000 mu of crops. Jianping County has 110,000 persons work on a crash basis and has sown 600,000 mu of improved varieties of crops to date, accounting for 30 percent of the farming acreage. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 1 May 82 SK]

RAINFALL REPORTS--Rain fell in many places of Liaoning Province on 28 April at the opportune time to combat drought and carry out spring farming. Precipitation calculated by 1600 on 28 April was 10 to 22 millimeters in Chaoyang Prefecture; 5 to 10 millimeters in Jinzhou, Fuxin, Tieling, Shenyang, Anshan and Yingkou; 1 to 3 millimeters in Dalian and Fushun; and below 1 millimeter in Benxi and Dandong. The rain would temporarily ease the drought in the western part of the province. But the drought is so serious that it is far from being relieved by the rain. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 28 Apr 82 SK]

FARM MARKETS--Urban and rural trade fairs in Liaoning Province enjoyed a good business during the usually slack first quarter. According to statistics on 1,159 trade fairs in 12 municipalities and prefectures, their aggregate volume of sales during the first quarter was 245 million yuan, an increase of 56 percent over the corresponding 1981 period. The average price of trade fairs dropped 4.04 percent from the level in the first quarter of 1981. [SK030501 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 1 May 82 SK]

PREVENTION OF FOREST FIRES URGED

SK291156 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 28 Apr 82

[Excerpts] According to our reporter (Li Runde), on the evening of 27 April the Nei Monggol Autonomous Regional People's Government sponsored an emergency telephone meeting to draw up plans for forest protection and forest fires prevention throughout the region. The meeting urged localities to sum up experiences gained in this regard, to strengthen their leadership over the work and to adopt effective measures to make further efforts to successfully prevent forest fires.

Shi Guanghua, vice chairman of the regional people's government, presided over the meeting and delivered a speech. Attending the meeting were responsible comrades from various league and municipal party and government organs and the regional-level departments and bureaus concerned.

The meeting noted: Since this spring, the region has scored remarkable achievements in preventing fires. Many advanced units and individuals have emerged in this work. However, the development of fire prevention work in various localities is not even. Leading cadres in some localities and units lack full understanding of the importance of fire prevention and have not exerted sufficient efforts to conduct education and propaganda work concerning the importance of fire prevention among the people. In addition, fire prevention organization is not perfect. Since 1 March, the region has consecutively experienced fires. According to initial statistics, 153 accidental fires have broken out throughout the region since the beginning of 1982, such as in (Ulanhada) commune in Jarud Banner, whose members caused a fire by boiling water at an outdoor area, burning 1 million mu of grassland, including 100,000 mu of forests.

To achieve good results, the meeting urged localities throughout the region to earnestly fulfill the following tasks:

1. Further efforts should be made to enhance leadership over the work of preventing fires.

2. It is necessary to earnestly draw a clear line of demarcation among areas which are responsible for preventing fire and enact fire-prevention responsibility systems.

3. Efforts should be made to earnestly do a good job in conducting education and propaganda work on the importance of fire prevention among the people and to strictly deal with the cases of accidental fires so as to ensure that fire prevention and forest protection can be carried out in line with the law.

4. Localities throughout the region should make further efforts to do a good job in the organizational, command and rear service work of putting out fires. Personnel who have caused great losses due to their ineffective action in putting out fires should be strictly dealt with.

5. The vicinity of pastoral residence areas, yurt villages and outdoor herding zones in various localities throughout the region should set up fire breaks with radius of 20-30 meters so as to guard the safety of herdsmen's property and lives and pastoral farms.

In conclusion, the meeting emphatically urged the people's government and departments concerned at all levels to earnestly implement various fire prevention measures with a high sense of responsibility and to take every possible means in fulfilling every fire prevention task so as to achieve smooth progress in realizing the four modernizations throughout the region.

FARM MACHINERY INDUSTRY READJUSTED

SK030527 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 2 May 82

[Excerpts] In view of the changes after the institution of various production responsibility systems in the rural and pastoral areas, the regional farm machinery industrial enterprises have readjusted the product mix, shifting the stress of mainly producing large- and medium-sized farm and animal husbandry machines and implements in the past to producing medium-sized and small farm and animal husbandry machines and implements and persisted in the orientation of serving farm and animal husbandry production and the needs of peasants and herdsmen to end the passive state in which many enterprises are operating under capacity and to create a vigorous new situation. Since the 3d Plenary session of the 11th CCP Central Committee, farm machinery enterprises throughout the region have eliminated the influence of the leftist ideology, implemented the production and construction principle of the regional CCP committee on developing the diversified economy with a stress on forestry and animal husbandry and earnestly readjusted the production of farm machinery industry to enable this industry to make big strides forward to serve the needs of the rural and pastoral areas and to serve the production and livelihood of the peasants and herdsmen, the diversified economy, the markets preparing for spring plowing and the export industry. Through readjustment, five changes have emerged in the regional farm machinery enterprises.

First, the production arrangements have become more rational. Since April 1979, the Nei Monggol farm machinery bureau in accordance with the needs of economic development has closed down, suspended and amalgamated a number of enterprises and urged some of them to convert to other trades, reduced the number of personnel and carried out necessary readjustment in the farm machinery industry. Through readjustment our region has cut 25 farm machinery enterprises, 6,700 staff and workers and 600 pieces of equipment so that the products produced have become more suitable for the needs of developing our region's agricultural, animal husbandry and forestry production.

Second, the production orientation has been readjusted. Products are produced in line with the sales volume so as to basically end stockpiling. In the first quarter of this year, the net sales volume of enterprises under the regional farm machinery bureau increased 49.7 percent over the corresponding 1981 period.

Third, the product mix has been readjusted to gear the needs of the rural and pastoral areas where the production responsibility system of setting farm output quotas on a household basis and the system of individual households assuming full responsibility are implemented. According to statistics compiled by 44 farm machinery enterprises last year, our region produced 15 varieties of medium-sized and small farm machines and implements totaling 147,000 to satisfy the needs of agricultural and animal husbandry production throughout the region.

Fourth, a number of new product varieties have been researched and produced.

Fifth, the quality of products has been improved. All enterprises have universally carried out technical and service activities. During the readjustment, farm machinery production enterprises throughout the region have attached primary importance to improving product quality to enable products to find good markets to achieve good economic results and to enliven the business of enterprises.

BRIEFS

COLD SPELL--According to the Nei Monggol weather station, a cold wave has entered Xinjiang from Siberia and will cause a drop in temperatures in most areas of our region on 25 and 26 April. The forecast calls for force-7 to force-8 westerly and northwesterly winds in northern areas of Alxa, Bayannur and Ulangab leagues, most areas of Xilin Gol League, and Hulun Buir, Xingan, Ju Ud and Jirem leagues. Temperatures in these areas will then drop 8 to 10 degrees. In other areas of our region, force-5 to force-6 westerly and northwesterly winds and a drop of 6 to 8 degrees in temperatures are forecast. [SK250444 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 24 Apr 82 SK]

SNOWFALL REPORT--Snow and rain fell in most parts of Nei Monggol region from 19 to 20 April. Snowfall and rainfall in the north pastoral areas was 2 to 3 millimeters. Precipitation in the southern areas was 3 to 10 millimeters. This is the first rain and snow in the region since the beginning of spring. It will help spring farming. [SK232217 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 22 Apr 82 SK]

OTOG BANNER LIVESTOCK--By the end of March, Otog Banner, Nei Monggol, produced 165,000 young animals, and 95.8 percent survived. [SK012212 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 30 Apr 82 SK]

XINGAN LEAGUE LIVESTOCK--Xingan League, Nei Monggol, achieved good results in spring livestock production. As of mid-April, the league had delivered over 300,000 young animals, and 87 percent survived. The death rate of animals decreased 50 percent from the corresponding 1981 period. [SK012209 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 30 Apr 82 SK]

ULANQAB LEAGUE WHEAT SOWING--Wheat sowing has basically been completed in Ulanqab League, Nei Monggol, as of 20 April. The league has sowed 4.25 million mu of wheat. [SK270400 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 26 Apr 82 SK]

QINGSHUIHE COUNTY AFFORESTATION--In Nei Monggol, Qingshuihe County has afforested some 32,600 mu this spring and planted 238,000 trees along roads and around houses, overfulfilling its annual targets. [SK292232 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 27 Apr 82 SK]

LI CHANG REPORTS ON RURAL ECONOMY

HK040650 Yinchuan NINGXIA RIBAO in Chinese 20 Apr 82 p 1

[Report: "Comrade Li Chang in His Report at Regional Cadre Meeting Proposes Bringing Into Play the Role of Science and Technology, Building Base Counties for Agricultural Modernization"]

[Text] Li Chang, adviser of the leading party group and executive chairman of the Presidium of the Chinese Academy of Sciences, gave a report in Yinchuan municipality on 17 April for the cadres and scientific workers at and above the department level of the Ningxia Hui Autonomous Region.

In his report, Comrade Li Chang analyzed the advantages for developing our regional economy and existing problems. After expounding on the aim of socialist social production, he pointed out: "From the viewpoint of promoting farm production and ensuring supplies, the present population growth rate in Ningxia is increasing too fast, and has already exceeded the rate of increase of grain output, which has resulted in an acute contradiction between supply and demand. Thus it can be said that tightening control over population growth has now become a strategic task of prime importance which is also the main way of tapping potential in the autonomous region. As for making full use of potential in Ningxia, it is necessary to further implement all party policies and improve the production responsibility system in agriculture as much as possible. Furthermore, it is necessary to bring into full play the role of science and technology and to organize and mobilize all scientific and technical personnel. Only by so doing can we tap the latent power of agricultural production in uncultivated areas and solve the contradictions between agriculture, forestry and livestock breeding, as well as promote diversified undertakings, improve circulation of commodities, promote a well-balanced ecological environment and do well in readjusting and restructuring industry.

After discussing the development of modern science and technology in his report, Comrade Li Chang stressed the importance of strengthening scientific and technical work. According to the present status and development needs in Ningxia, he put forward five suggestions for promoting scientific and technical work: 1) emphatically tackling subjects which are appropriate to economic and social development in Ningxia and selecting a proper technological structure for overall development; 2) promoting science in a systematic way and enhancing managerial level; 3) setting up research centers first on subjects related to accelerating agricultural modernization and then gradually on science and technology; 4) uniting all scientific and technical personnel and convincing persons from Beijing, Shanghai and other large municipalities to come to Ningxia for short- or long-term work and academic activities; 5) strengthening higher education and adult education in the autonomous region and establishing a system for promoting scientific and technical activities among the masses of people in urban and rural areas.

Comrade Li Chang then made an analysis and spoke briefly on the situation in Yanchi and Guyuan counties which have been selected as two trial base counties for agricultural modernization by the Chinese Academy of Sciences with coordination of the leadership at the autonomous region, prefecture and county levels. He then pointed out: "Agricultural modernization involves comprehensive application of modern science and technology and overall development of agriculture, forestry, animal husbandry, industry and commerce by absorbing or improving the traditional method of plowing. This also [word indistinct] to creating a well-balanced ecological environment and steady development of rural economy." He also pointed out: "Over the past few years, comprehensive investigations of agricultural natural resources have been made, and relevant work has been accomplished in agricultural regionalization in Yanchi and Guyuan counties. A correct principle of developing farm production has been set and gratifying successes have been scored at key trial sites. Now efforts will be made to set up some more key trial sites according to plan throughout the two counties. Thus we will be able to promote overall economic development in all counties by drawing on the experiences gained from these key sites and step by step put an end to the grave situation where yield is always low in areas of extensive cultivation, and where the more land reclaimed, the greater the waste. We must, on the one hand, promote agriculture, forestry, animal husbandry and rural sideline production in an all-round way. On the other hand, we must develop agricultural production, industry and commerce simultaneously. No big advance can be made in rural economy unless development is made in both respects.

In his report, Comrade Li Chang proposed that attention be paid to planned parenthood and control over population growth in the base counties for agricultural modernization. At the same time, efforts should be made to raise grain output and average income of commune members to the highest possible level in similar counties in drought and semi-drought areas and in loess plateau. Proper readjustment should be made to farm production in vast areas of extensive planting by using modern technology. Improvement must be made to the ecological environment so as to put an end to the grave situation in land utilization. It is also necessary to continue to raise the level of science and technology in the region and cultivate wisdom among the people so that agricultural production can be further developed during the Seventh 5-Year Plan.

On the basis of the practical experiences gained in the past few years from the whole country, Comrade Li Chang put forth the following six suggestions for methods of working on the new experiments in agricultural modernization: 1) under the party's leadership, leaders at all levels, experts and the masses must be integrated. In applying science and technology, local experts and scientific and technical personnel must seek help and advice from scientists. 2) Scientific workers in all fields must pool their efforts and strengthen their cooperation for tackling key problems in science and technology. 3) In the base counties for agricultural modernization, modernization must be aimed at helping peasants to become affluent so that immediate interests can also be satisfied in the long-term plan. 4) It is necessary to make comprehensive investigations in all areas by making some breakthroughs at the experimental key sites, to promote modernization in the base counties by first drawing on experiences from some experimental key sites, and then promoting them in all similar counties of the autonomous region and the drought areas in loess plateau. 5) It is necessary to set up a technological system to train technical personnel as reserve forces. 6) In the base counties for agricultural modernization, it is necessary to strengthen the building of socialist cultural civilization together with the building of socialist material civilization so as to build up a new-type countryside of socialism.

CLASSIC INDICATORS OF ECONOMIC RESULTS FROM AGRICULTURE DISCUSSED

Chengdu SICHUAN RIBAO in Chinese 21 Jan 82 p 2

[Article by Wen Yanwen [3306 4282 2429]: "Efforts to Improve Results in The Agricultural Economy"]

[Text] At the moment, while continuing to make the rural economy prosper, how to improve results in the agricultural economy is a problem requiring diligent study and solution. Not long ago, Wenjiang Prefecture held a discussion meeting on economic results problems in the agricultural economy, which was devoted to preliminary study and discussion. This played a positive role in improving perceptions, in the exchange of experiences, and in promoting work.

Improvement of Results in the Agricultural Economy Is an Urgent Matter

Since the founding of the People's Republic, agricultural production in Wenjiang Prefecture has seen substantial growth; however, the not very good benefits from the agricultural economy has been a long enduring problem. In the past, as a result of the effects of "leftist" ideology, for a long period of time the mistaken "figuring up the political bill without figuring up the economic bill," whereby production was carried on without calculation of costs and attention was devoted to increasing production but not to increasing earnings, led to the appearance of "high output brigades that were poor," and slow rise in prosperity. Such "caring only that the lamp gives light with no regard for how much oil it consumes," in disregard of economic benefits has still not been thoroughly eradicated in some places. The several main criteria for economic results from agriculture used during the 10 years of turmoil all showed decline. Comparison of 1976 with 1966 showed that despite a 21 percent increase in total earnings from agriculture and sideline occupations throughout the prefecture, net earnings (meaning gross earnings minus production costs) had declined by 1 percent, and results derived from investment (meaning net earnings created for each yuan invested) had fallen by 37.9 percent. Results of investment of labor in agriculture (meaning net earnings produced per workday) fell 39 percent, and average net earnings of the agricultural population) fell 25 percent. With the smashing of the "gang of four," and particularly following implementation of the spirit of the 3rd Plenary Session of the 11th Party Central Committee, remarkable changes took place in the situation. Nevertheless, results in the agricultural economy continued not good, the reason being that the extent of increases in investment of funds and labor exceeded or approached the extent of increase in net earnings. Despite the rise in actual benefits received from investments of funds and labor in 1979 as compared with 1976, 1966's levels were not attained, and the 1980 returns on investments in funds continue to decline from those of the previous year. The reason that average per capita earnings in 1979 were 21 percent greater than in 1966 and that another increase took place in 1980 was, apart from the factor of a rise in prices paid for agricultural products, the fundamental lack of increase in the agricultural population resulting from the launching of planned parenthood work during the past several years.

Benefits derived from the agricultural economy directly affect the level of distributions by units in the collective economy. Good results in the agricultural economy mean development of production, and are manifested in the strength of the collective economy and increase in commune member earnings. A comparison of the entire prefecture with 6 "golden flower production teams" in which average per capita earnings distributions in 1979 amounted to more than 300 yuan, including the 4th Production Team of the 1st Production Brigade of Guihu Commune in Xindu County and the 4th Production Team of the 6th Production Brigade of Siping Commune in Shifang County, showed the following: In the 6 production teams, net earnings per yuan of investment were 2.17 times those in the prefecture as a whole, and net earnings per workday were 1.69 times higher. As a result, average per capita earnings were 2.03 times higher than for the prefecture as a whole, and average per capita distribution of earnings to commune members (including returns for manure provided), and the value of a day's work were respectively 1.64 times and 1.91 times higher. Looked at in terms of average per capita net earnings as a ratio of average per capita gross earnings, the percentage averaged 81.6 percent for the 6 production teams, and only 59.5 percent for the prefecture as a whole. From this may be seen that with continued eradication of the influence of "leftist" ideology, efforts to increase economic benefits from agriculture for the prefecture as a whole offer a very great potential and are an urgent task.

How to Measure the Economic Results of an Agricultural Production Unit

What is meant by economic results from agriculture is the relationship between "input" and "output," i.e., making a relatively small expenditure to obtain fairly large economic benefits. A current yardstick used for measuring economic results from agriculture that is used in some places is the productivity rate of agricultural labor. Some places use benefits per unit of investment, and some use soil productivity rate, etc., each method being valid. We believe that measurement based on average per capita net income is fairly accurate and equitable, and also handy to use. The formula is as follows:

An agricultural production unit's economic results = net earnings in a given year (gross earnings in a given year - production costs for the given year) + agricultural population for the given year. Use of this formua has the following principal advantages.

First it requires optimum benefits from investment of funds. "Net earnings" mean all the wealth created in any given year by an agricultural production unit. Use of the amount of average earnings of the agricultural population of a unit to determine economic results requires economy in and maximum equitability in investment of funds, so that total net earnings will increase to the maximum extent possible. Thus, economy in the investment of funds has to be done while increasing production rather than done negatively in order to increase economic benefits per unit of investment of funds.

Second, it reflects requirements for increase in the labor productivity rate. In every agricultural production unit, the ratio of population to work force is roughly the same; consequently, the amount of average per capita earnings also forms a rough ratio with the same amount of labor productivity. Increase in average per capita net earnings inevitably will require an increase in labor productivity. Conservation in the use of labor must likewise be done while increasing total output or total earnings, rather than be done negatively on the basis of the economic benefits derived from time per unit of labor.

Third, it is able to show in a comprehensive way the levels of production and the levels of management of an agricultural production unit. It requires that things be done in accordance with natural laws and economic laws, that advantages be used to the full, that avenues for production be opened, that advanced techniques be extended, and that the commodity production rate be increased. At the same time, in both the "broadening of sources of income," and "reducing expenditures, scientific management must be diligently practiced and systems of responsibility established to promote growth of production.

Broadening of Source of Income and Reducing Expenditures To Increase Results in the Agricultural Economy

The issue of improvement in results from the agricultural economy has fairly widespread ramifications. Looked at in terms of practical experience, basic key points should keep their eyes on the broadening of sources of income and reducing expenditures, devoting greater efforts to energetic development of agricultural sideline production to increase social wealth.

First, production patterns and the economic structure has to be equitably readjusted for a gradual transformation of the natural economy or the semi-natural economy into a predominantly social commodity economy in a new type agricultural economic system. The crux of improvement in economic results from agriculture lies in an all-around rise in agricultural production, the principal indicators of which are increases in the labor productivity rate, the soil productivity rate and the commodity production rate. The experience of numerous outstanding communes and brigades illustrates that the former agricultural economic structure of sole emphasis on grain militated against improvement in the economic results of production teams. Only through establishment of concepts of "large-scale agriculture," "large-scale production of grain," the adaptation of general methods to local situations, equitable readjustments, making the most of advantages, and vigorous development of economic diversification even while continuing to devote serious attention to grainproduction, taking the road of all-around development of agricultural sideline industries can poverty be overcome and prosperity be attained rapidly.

Second, a good job of cost accounting for production has to be done, with adherence to a program of thrift in the operation of communes, a strict system of financial management, efforts made to lower production costs, and use of the minimum expenditures to gain maximum economic results. The practice of numerous communes and brigades has demonstrated that agricultural production requires payment of an irreducible price. As production grows, certain necessary expenses will rise. However, the extent of increase in expenses must be smaller than the extent of increase in output and output value. If they are not, economic results will be impaired. In numerous production teams today, the utilization rate for farm machines and equipment is not high; chemical fertilizers and pesticides are not being applied properly; management of materials is not being attended to; waste is serious; production expenses have greatly increased; and net earnings have declined commensurately, which means real impairment in economic results from agriculture. It should also be pointed out that formerly some of our comrades did not factor expenditure of human labor into production costs, and the squandering of human labor was everwhere serious. The masses said, "It is not the hard work, but working for nothing that we fear." Consequently, in fugure agricultural production, in farm mechanization and capital construction of agriculture, certainly manpower, resources, financial resources, and material resources, are to be treasured to the greatest extent. There can be no arbitrary practice of giving blind commands, doing work that produces no benefit, or doing stupid jobs that provide no repayment.

Third is the need to establish strict systems of responsibility for production to make full use of the positive role of rural talent and science and technology. Commune members are masters of production teams. Getting economic results from the agricultural economy requires reliance on their enthusiasm and initiative, and making the most of their intelligence and ingenuity. Moreover, establishment of systems of responsibility for production, equitable use of human talent, and extension of advanced techniques are mutually supportive. They are able to make commune members better develop their talents to create wealth, and to win optimum economic benefits.

Naturally there is more to improving the economic results of agriculture than the preceding alone. There are tasks in other areas that also require attention. Furthermore, this is not solely a matter for production teams; upper echelon leaders and the various departments that have something to do with "agriculture" also have to create conditions for this. Only in this way can the economic results of agriculture as a whole be improved.

WANG ENMAO INSPECTS SOUTHERN RURAL AREAS

HK261418 Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 25 Apr 82

[Summary] While Xinjiang Regional CCP Committee First Secretary Wang Enmao was recently inspecting rural areas in the south Xinjiang region, he stressed: "In carrying out agricultural capital construction in Xinjiang, it is essential to adhere to the "five-goods," namely: setting up good strips of land for mechanized farming and building good channels, good roads, good forest belts and good management centers, to ensure comprehensive control over mountains, rivers, fields, forests, roads and villages. We must build the rural areas in Xinjiang into new and prosperous socialist rural areas where people live and work in peace and contentment."

At the beginning and in the middle of April, Wang Enmao and Amudun Niyaz, vice chairman of the regional people's government, went to Bayingolin Monggol Autonomous Prefecture and Hotan and Kashi Prefectures to inspect work. They conducted investigations and came to the following conclusion: In places which have perfected all forms of production responsibility systems and practically and realistically carried out farmland and water conservation capital construction, agricultural production has quickly developed, commune members' livelihood has greatly improved and their rural appearance has undergone a relatively great change." Wang Enmao said to cadres and the masses of various nationalities: "At present, we must sum up the experiences in implementing agricultural production responsibility system in rural areas, perfect the agricultural production responsibility system and stabilize it. To further develop agricultural production, we must not only devote ourselves to the responsibility system but must work hard to develop production." He said that before the Great Cultural Revolution, the regional CCP committee had put forth that in building rural areas, it was necessary to set up good strips of land for mechanized farming and build good channels, good roads, good forest belts and good management centers. After a long period of practice, the "five-goods" conforms to the reality of the region and is beneficial to the development of production and the improvement of people's livelihood. People have welcomed it. The "five-goods" must not only be restored but must also develop.

He said: "In building 'five-goods' rural areas, it is most important to build good water conservation projects, build good channels which are capable of irrigation and drainage, to level the ground well and set up strips of land well so that mechanized farming can be carried out on them. We must make even greater efforts to plant more trees. We must not only increase the number of trees but also improve the quality of trees. We must strengthen our ability to protect farmland and pastures from wind and sand. We must repair roads well." He also said that while building the "five-goods" rural areas, it is also necessary to build urban areas well. The region must formulate plans for building roads in urban areas well. In the future, houses must not be indiscriminately built in urban areas but must be built in accordance with the plans. After the region builds "five-goods" rural areas, production will develop, accumulation of collectives and peasants' income will increase and their livelihood will improve.

'XINJIANG RADIO' URGES BETTER RURAL LEADERSHIP

HK030354 Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 2 May 82

[Station commentary: "Get a Good Grasp of Building Rural Production Team Leadership Groups"]

[Excerpt] The rural and pastoral areas of Xinjiang have instituted various types of production responsibility systems since the third plenary session, scoring notable results. The peasant masses have hailed the excellence of party policies.

However, in the wake of the changes in rural managment, some production team cadres hold that they have nothing to do since the institution of the systems of assigning fixed production quotas to each household or assigning the land to each household in exchange for fixed levies. They dare not work in a bold way or do anything about behavior that damages collective property. As a result some production teams are in a state of paralysis with nobody grasping production or looking after collective property. In these circumstances, it is essential to solve the serious questions of how the rural grassroots cadres can do their work well and how to bring into full play the functions of the production teams.

The rural brigades and production teams are collective [words indistinct] that shoulder important economic and political functions. The production teams are responsible for distribution and the fulfillment of contracts, and have to take good care of collective property. They have to formulate production plans over the whole year, fulfill the state procurement quotas, carry out yearend distribution, and look after the dependents of martyrs and servicemen, five-guarantee households and so on. As grassroots rural political power organizations, they have to promote social order, uphold the law, mediate in civil disputes, and grasp militia training, planned parenthood, public education and so on.

None of these tasks can be discarded following the institution of production responsibility systems. Moreover, due to the changes in management forms, it is also necessary to change some work methods, and some work has to be done more carefully. This means that the burdens of the rural cadres are heavier, not lighter, and the demands on them are higher than before. The role of the production team can only be strengthened, not weakened.

The key to bringing into play the role of the production teams lies in building their leadership groups. It is necessary to conduct rectification in a planned way in certain lax, paralyzed and semi-paralyzed teams, and readjust their leadership groups. We must follow the mass line and elect to the leadership groups comrades in the prime of life who have good ideology and work style, resolutely implement party policies, know how to manage, and possess cultural knowledge. We must establish post responsibility systems for cadres. We must commend and reward cadres who work well and score achievements, and criticize and educate those who do not work well. We must train the production team cadres in a planned way, and organize them to study the party's principles and policies, scientific agricultural knowledge, and advanced management experiences, and improve their work ability.

PEOPLE'S LIVING STANDARDS IMPROVE

HK271035 Kunming Yunnan Provincial Service in Mandarin 1100 GMT 24 Apr 82

[Summary] The Yunnan Provincial Statistical Bureau conducted a survey of the financial situation of 610 commune-member households in 28 counties in the province, including embankment areas, mountainous areas, inland and border areas. The results of the survey revealed that last year, after the principles and policies of the party were further implemented, all forms of production responsibility systems were established and perfected and scientific farming was carried out, agricultural production quickly developed, commune members' income constantly increased and their livelihood improved.

"The average amount of grain allocated by the collectives to each person of the 610 commune-member households last year was 6 percent more than in the preceding year and the per capital net income obtained from the collectives was 80 yuan, 3.4 percent more than in the preceding year." The income of commune-members households increased relatively greatly, the number of well-off households increased and the number of poor households was reduced. "Last year, the per capita total income of the 610 commune-member households reached 202.9 yuan, 34.4 yuan more than in the preceding year, an increase of 20.4 percent. After deducting the charges spend on commune-members households sideline production and taxes, the per capita net income was 178.1 yuan, 30.4 yuan more than in the preceding year, an increase of 20.6 percent." The living standards of commune members improved. "Last year, of the net income of the 610 commune-member households, the per capita cash income reached 113.6 yuan, 30.5 yuan more than in the preceding year, an increase of 36.7 percent. After their cash income increased, their ability to purchase commodities increased correspondingly. Last year, each person spent an average of 86.1 yuan in cash on commodities. Of this 86.1 yuan, each person spent an average of 65 yuan on consumer goods, 13.8 yuan more than in the preceding year, an increase of 26.9 percent; each person spent an average 21.1 yuan in cash on means of production, 10 yuan more than in the preceding year, an increase of 90.1 percent." The number of bicycles, sewing machines, radios and watches owned by the commune members by the end of last year was 40.6 percent, 29.3 percent, 24.6 percent and 46.5 percent respectively more than in the preceding year.

From the survey, we can also see that the level of income of some commune members was still relatively low and their livelihood was still difficult. Of the 610 commune-member households, the number of households whose per capita net income last year was less than 80 yuan was 36, accounting for 5.9 percent. The majority of these households in difficulties are scattered in minority nationality border areas and inland mountainous areas. In future, we must support them economically and help them develop production.

BRIEFS

FOREST FIRE CIRCULAR--The Yunnan Provincial People's Government recently issued an urgent circular on prevention of forest fire. The circular demands that all places throughout the province take vigorous measures to prevent forest fires. The circular says that since the beginning of this year, forest fires in the province have been very serious. The number of forest fire accidents throughout the province by the end of March was 16.7 percent more than in the corresponding period of last year and the areas affected by forest fires were 21 percent more than in the same period last year. The province incurred economic losses of some 2.3 million yuan. In some places, villages were burnt and people and livestock were killed by forest fires. The circular demands that governments at all levels strengthen leadership over the protection of forests and the prevention of fire and in the light of the actual situation, conduct inspection and make specific arrangements. From now on, all prefectures, autonomous prefectures, municipalities and counties must each assign a principal leading cadre to take charge of this work. Communes, brigades and production teams must also assign people to take charge of this work. [Kunming Yunnan Provincial Service in Mandarin 1100 GMT 20 Apr 82 HK]

STATE FARM, LAND RECLAMATION SYSTEM TASKS FOR 1982 CHARTED

Beijing ZHONGGUO NONGMIN BAO in Chinese 25 Feb 82 p 1

[Article by Yu Xin [0060 2450]: "State Farm and Land Reclamation System To Have New Production Breakthroughs This Year. Conference of State Farm and Land Reclamation Bureau Directors Throughout the Country Summarizes Four Fundamental Experiences"]

[Text] Gao Yang [7559 2799], minister of the Ministry of State Farms and Land Reclamation said at a national conference of state farm and land reclamation department and bureau directors held in mid-February that "this year we will act in the spirit of Comrade Zhao Ziyang's government work report to the 4th Session of the 5th National People's Congress and on the basis of the fundamental experiences of more than 30 years of farm and land reclamation work to emphasize readjustment and reorganization of state farm and land reclamation production and construction for genuine increase in economic benefits and strive for new breakthroughs during 1982 in state farm and land reclamation production and construction throughout the country."

After more than 30 years of development and construction, state farm and land reclamation endeavors are a force that cannot be ignored in the national economy. Nationally the state farm and land reclamation system's commodity grain rate is about 60 percent; its natural rubber output accounts for 90 percent of the national total; 80 percent of the supply of fresh milk to large and medium-size cities comes from the state farm and land reclamation system. Consequently, further development of state farm and land reclamation endeavors possesses important significance for increasing the country's economic strength and improving the people's livelihood.

Summary of more than 30 years of state farm and land reclamation endeavors brought out four fundamental experiences. First was the need to define the goals of operating socialist farms. Production and construction must take into consideration natural conditions and economic results with economic accounting being done strictly in accordance with requirements for operating enterprises in order to provide, to the maximum extent possible, products and profits to the country. Second, state farms must move from unitary operations to multiple agricultural, industrial, and commercial operations. Third was strict practice of the principle of distributions according to work to arouse the enthusiasm of staff and workers and to increase the labor productivity rate. Fourth was that only through attaching major importance to the application of modern agricultural science and technology and scientific management methods can state farming and land reclamation be modernized.

A look back at historical experiences shows that in order to develop a fine situation in state farm and land reclamation, the focus this year should go to reorganization of enterprises to increase economic benefits, giving attention to the following several tasks: (1) Further perfection of production responsibility systems, with proper setting of production criteria, cost criteria, labor quotas, and proportional distribution of profits in the practice of production responsibility systems. Achievement of proper handling of the relationship among the state, the collective, and individuals, both arousing the enthusiasm of staff and workers and not adding hardships for the state through reckless issuance of bonuses. (2) Active development of economic diversification. Specific measures for development should be worked out on the basis of the new situation and the new problems that have emerged for production from industry, the rubber growing industry, the animal husbandry industry, and the fruit tree industry. In the course of their development, combined agricultural, industrial, and commercial enterprises should devote attention to organization of production that breaks through regional and trade and industry boundaries. (3) Increase in farm staff and worker cultural and scientific levels in the promotion of modernization of farm production. (4) Strict economic accounting. Devote urgent efforts to the build up and continued training of upper and middle-ranking financial accounting cadres for a gradual contraction of all unreasonable expenditures and a decline in production costs for genuine increase in economic benefits from enterprises. (5) Improvement in farm leadership. On the principles of socialist enterprise management to hold staff and worker congresses, to build systems of responsibility for plant managers in fact as well as in name, and institute effective management of enterprises.

State farm and land reclamation department and bureau directors attending the conference from the various provinces, municipalities, and autonomous regions indicated their desire to take in hand an all-around reorganization to tap fully enterprise potential, to strive to fulfill and overfulfill this year's production and construction plans, and to develop a fine situation in state farm and land reclamation.

WHEAT FOR PRC--China has placed its largest order for Canadian wheat in history and it is worth more than $2 billion. The 3-year contract replaces one of similar length and starts on 1 August. China has agreed to buy between 3.5 million and 4.2 million metric tons of wheat, under the previous contract Canada sold China between 2.8 million and 3.5 million tons. China is the second largest purchaser of Canadian wheat after the Soviet Union, which buys an average of 5 million tons a year. EXHORTATIONS ISSUED FOR EARLY SPRING CARE OF OVERWINTERING CROPS

Beijing ZHONGGUO NONGMIN BAO in Chinese 21 Feb 82 p 2

[Article: "Good Care of Overwintering Crops To Win Bumper Summer Grain Harvest"]

[Text] Summer grain and oil-bearing crop production occupy a major position in agricultural production for the whole year, their outputs amounting to 20 percent and 40 percent respectively of total annual output of grain and oil-bearing crops. This year, when the state wants grain output to exceed all-time highs, winning a new breakthrough in summer grain seems ever more important.

Because of the general establishment of various forms of production responsibility systems at sowing time last fall and winter quality of sowing was generally pretty good, and both fertilizer and fine varieties were more numerous than in previous years. Postplanting fertilization, cultivation, raking and rolling of the soil, and winter watering were done over a wider area than during 1981. However, conspicuous problems are the continued decline in the wheat growing area, the large ratio of late-sown to total area, and seedling condition prior to winter's onset not as good as in previous years in most places. Moreover, in north China, the continuous autumn and winter drought has been bad for summer grain production, and though seedling condition took a turn for the better recently, it still does not meet requirements for a bumper harvest. Right now is the time when the winter and spring seasons meet. It is an important time for growth and change in overwintering crops, and strict attention must be given to care of overwintering crops during this period to promote change in seedling conditions to lay a foundation for a bumper summer harvest.

How should good spring care be given? It is necessary to start with this spring's climatic characteristics and the seedling growth situation at the present time, adopting measures to the present time and local situations. Ever since last December, the climate has everywhere been rather warm. In north China the frozen soil horizon has been shallower than in former years, and greening up has tended to be early. It is necessary to give timely early care on the basis of different circumstances, to stabilize the sturdy seedlings that grew before the onset of winter, and to promote new tillering during the spring season to increase the wheat heading rate, to increase the number of grains, and to increase grain weight. For third category seedlings and late growing seedlings, it is particularly necessary to provide care with fertilizer and water so they resume growth and joint, making the wheat seedlings change to a higher grade. The protracted drought in north China poses a serious threat, and every possible means should be used to combat drought and preserve soil moisture through timely hoeing, raking and compacting of the soil. In addition fullest use should be made of all water conservancy facilities to expand the spring irrigated area. The continuous huge downpours of rain south of the Chang Jiang require prompt clearing of ditches and drainage to prevent water stagnation and waterlogging. Vigilance should also be increased against the possibility of a return of coldness in spring and against other diseases and insect pest catastrophes, preparations being made for prompt prevention and control.

A major link in doing a good job of spring care is to combine mass enthusiasm and scientific technique. Following institution of production responsibility systems, mass enthusiasm for wheatfield care is very high, but technical guidance must be improved to prevent blindness. There is need to use the strength of all kinds of technical promotion and technical service organization, and through various methods such as giving short training periods to teach techniques, to increase levels of scientific care. Departments concerned should promptly assure supply of the fuels, electric power, and other materials needed to guard against and combat disasters and to give spring care. Production teams should also increase organization. They should not simply allow individual families and households to act on their own, wasting manpower and time.

Now the "rainwater period" [around 19 February] has passed, and all jurisdictions should educate commune members to get over the old habit of a "mad January and an idle February" to concentrate needed work forces so that while devoting attention to preparing for spring farming, they do a good job of caring for crops to be harvested in summer to win a bumper harvest of summer grain and oil-bearing crops.

PUBLICATION'S ROLE AS SCIENTIFIC KNOWLEDGE PURVEYOR UNDERSCORED

Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 1, 1982 p 1

[Article by the Editorial Department: "Willingly Be Green Leaves That Set Off Red Flowers"]

[Excerpts] The year 1982 has arrived. Accompanying the arrival of the new year is the emergence of a fine situation throughout the country. The line, programs, and policies of the 3d Plenary Session of the 11th Party Central Committee have seen success in every field, no place more than in rural villages.

Some comrades believe that a general "shift in focus" should also take place in NONGCUN KEXUE the emphasis changing from basic knowledge to promotion of applied technology, and lacking this it will become divorced from rural realities. Such a view is not unreasonable. Serious attention to and intensification of the general promotion of applied technology are indeed urgent matters in the spread of science to rural villages today. Very good evidence of this may be found in Shandong's promotion of "Lumian No 1" cotton, Henan's promotion of techniques with wheat that produce yields that are "high, consistent, and low in cost," and promotion of hybrid rice throughout the country's rice growing regions, all of which have won outstanding results. However, one should not come to the conclusion from this that "rural villages do not need basic scientific and technical knowledge." On the contrary, a look back at the development of China's agriculture over the past more than 30 years provides a very extensive lesson, namely that it has been lack of basic knowledge about agricultural production that has resulted in contravention of natural laws and economic laws, and has led to a series of blind leadership.

For example, because of a lack of understanding of the principles of the material cycle and of energy transformation, the idealistic slogan of "the land will produce whatever man has the courage to take," unexpectedly confused and poisoned people's minds and was popular for a time. The blind introduction of high yield varieties in the pursuit of multiple cropping indices without concern for sufficiency in water and fertilizer to support them, exists in many places and has led to disappointments and results which are the opposite of those desired.

In another example, because of the lack of understanding of the laws of ecological balance, in many places in China, farming, forestry, animal husbandry, and fisheries are practicing plunder. They make much use of, but give little nurture to the cultivated land, taking much and returning little, leading to a decline in soil fertility. Reckless cutting and denudation of forest resources, taking much but afforesting little has caused increasingly severe erosion. Overgrazing of grasslands, taking only but not replacing, has created degeneration in large areas of the grasslands, and in some places desertification has set in. Overfishing and indiscriminate fishing has led to increasing exhaustion of aquatic product resources. Such a plundering has destroyed the natural ecological balance and caused agricultural production to devolve into a vicious cycle that brings tragic consequences.

Consequently, our view is that rural villages need both applied technology and basic knowledge. Current vigorous efforts to intensify promotion of applied technology are extremely important, and spread of basic knowledge should not be neglected either. Large numbers of specialized periodicals of various kinds are already focusing on applied technology, NONGCUN KEXUE will serve as a publication oriented toward overall popularization of science in rural villages. It will continue to maintain an emphasis on the spread of basic knowledge, which is also necessary. In this new year, we should "willingly be green leaves that set off the red flowers," working together with the broad masses of readers and writers, the better to practice the five sentences [open the door of knowledge for readers; give advice regarding production; provide new material for learning; give guidance for readers' livelihood; and make contributions toward four modernizations in rural areas] put forward at the time that the publication changed its name, so that during this period of steady upsurge in the "craze for science" in rural villages, it will genuinely be able to make the most of the role that it should play.

STATE SUPPORT, PEASANT INCOME RELATIONSHIP ANALYZED

Fuzhou FUJIAN RIBAO in Chinese 19 Feb 82 p 3

[Article by Gu Deqi [7357 1795 3823]: "Peasants' Income Increase and State Support"]

[Text] After 1976, and particularly since the party's Third Plenum, the party and the people's government, in order to mobilize the enthusiasm of rural communes and brigades and the peasants' production, have made appropriate readjustments in agricultural production relationships, universally put into effect an agricultural production system of responsibility, raised the procurement prices for agricultural and sideline products considerably, reduced agricultural taxes, liberalized all the various economic policies in effect in the countryside, promoted the development of production, and brought about a considerable increase in peasant incomes.

Over the Past Few Years the Income of Peasants Has Increased Rapidly

First of all, in each of the past 4 years the procurement prices of agricultural and sideline products have been raised. In our province in the 2 years 1978 and 1979 the procurement prices of 93 varieties of products were raised, including grains, edible oils, meat, aquatic products, dried and fresh fruit, and local sideline products, representing a 27.6 percent rise in the general level of prices. In 1980 the procurement prices of 27 varieties of products were raised, including cotton, jute, sun-cured tobacco, sugar cane, and lumber. In the first half of 1981 the procurement prices of six products were increased, including flue-cured tobacco, and in the second half of the year the procurement prices for lumber and bamboo were also raised. The state's raising of procurement prices for agricultural and sideline products by a comparatively big margin over the past 4 years has enabled peasants, beginning with 1982, to derive a yearly profit of over 560 million yuan.

Secondly, the price increases and negotiated prices for agricultural and sideline products that exceed the base procurement price can enable the income of peasants to be increased by approximately 100 million yuan each year. In 1980 peasants, through price increases and negotiated prices for agricultural and sideline products, increased their income by 75.79 million yuan, of which 17.46 million yuan represents price increases for state brands and 58.31 million yuan represents income from negotiated prices for the various agricultural and sideline products. According to the estimate of concerned departments, peasants' increased income from price increases and negotiated prices for 1981 is 143.81 million yuan.

Third, rural tax revenues have been reduced. Each year reduced revenues are reduced by up to over 30 million yuan, representing 16 million yuan in agricultural tax exemptions at tax-collection sites throughout the country, and over 14 million yuan in reduced industrial and commercial taxes at commune and brigade-run enterprises in the countryside.

Fourth, agricultural trade markets have been liberalized, enabling peasants to increase their income by from 200 to 300 million yuan each year. According to the estimate of concerned provincial departments, peasant income in 1980 from the sale of agricultural and sideline products at agricultural trade markets in cities and towns was over 244 million yuan, and that for 1981 was approximately 300 million yuan.

The Fostering and Support of Agriculture By the State and the Various Departments

In this period of the readjustment of our national economy, in order to build up our agricultural base as quickly as possible and speed up the development of agricultural production, the state has expended a great deal of effort to foster and support agriculture. The amount of capital our province uses for agriculture is between 300 and 400 million yuan a year, representing about 25 percent of total budgeted expenditures for a given year. In 1978, the amount reached over 384 million yuan; in 1979, it reached over 431 million yuan; in 1980; it was over 348 million yuan; and in 1981 it was around 360 million yuan. In addition. the proportion of the province's finances utilized each year for projects directly supporting agriculture such as farmland and hydraulic capital construction and all kinds of agricultural operating expenses, capital for developing the potential of and renovating enterprises, expenses for the simple farm construction, the costs for the three items of agriculture, science and technology, increased allotment of circulating capital, and expenses for educated youth to go to the countryside to work, is generally about 22 percent of total expenditures. In 1978, over 335 million yuan was spent on projects directly supporting agriculture; in 1979, over 375 million; and in 1980, over 328 million yuan. Aside from this, between 40 and 50 million yuan each year is allocated to support capital construction in agricultural and industry and other projects indirectly supporting agriculture.

According to incomplete statistics, the support given various branches of the national economy to agriculture is approximately 100 million yuan each year. Taking 1980 as an example, the province's department of finance, in addition to raising prices and alloting expenditures to directly support agriculture, also provided about 70 million yuan to cover all kinds of subsidies and losses of which the most important were 15 million yuan in state quota subsidies for chemical fertilizer, and 14 million yuan in phosphate fertilizer subsidies for special cooperative projects outside the province. Price quota subsidies and loss subsidies for agricultural machinery together totaled over 5.8 million yuan; pigskin and cowhide production procurement subsidies amounted to 13.6 million yuan; for the aquatic products industry, subsidies for the production of kelp glue and for goods and materials required by the fishing industry amounted to 8.9 million yuan; subsidies for losses in the agricultural, forest products, livestock, and fisheries markets amounted to 8.5 million yuan, and so forth and so on. The subsidies on the losses from firewood, cooking oil, plastic film, bamboo and lumber, as well as small- and medium-sized farm implements used in agriculture, as a result of the special pricing by the departments of commerce and supply and marketing amounted to over 25 million yuan. In addition, the price for electricity used domestically and for production in the countryside has been low, enabling communes and brigades, and peasants to benefit either directly or indirectly.

Several Points of Understanding

First of all, in developing the rural economy, we must rely constantly on the party's policies and scientific methods. At the same time, we must also do a good job of managing and utilizing all presently-existing agricultural capital, so as to bring its greatest economic effectiveness into play. Following the Third Plenum of the CCP Central Committee, the state used its greatest efforts to increase capital investment for agriculture, providing agriculture with immense support both financially and materially. Under the present circumstances of the state being in relative financial difficulties, hereafter it will not be possible, in any given year, to invest even more capital in agriculture; we can only do the best we can to do a good job of managing and utilizing the agricultural capital that already exists. At present the economic effectiveness of the capital funds invested in support of agriculture is still comparatively poor, and there is a lot of waste; for this reason, its potential is still very great.

Secondly, regarding the procurement prices of agricultural and sideline products we must adopt the guiding principles of basic stability and adjustment on an individual basis. Although, through many price adjustments, there has been an obvious reduction in price differentials for industrial and agricultural products, nevertheless some still exist. This problem will take a long time to solve if we base ourselves on the actual conditions in our country and our province, and if we move gradually in a manner that is consistent with our actual capabilities. The overall situation in price relations, affecting so many other aspects of life, is rather complex; the peasants' benefit must be considered; the benefit of city dwellers, and that of workers and staff must also be considered; and so must the benefit of our country. At present, our province's agricultural tax which, following the tax reductions, only represents less than 6 percent of the total agricultural output, has in each of the past 4 years increased peasant earnings by over 500 million yuan, while over this same period our national income has increased by only 700 million yuan. For this reason, on the basis of our country's present financial circumstances, over the next 3 to 5 years it will not be possible to raise the procurement prices of agricultural and sideline products again, and we must adopt instead the guiding principles of basic stability and adjustment on an individual basis. Increasing peasant income depends mainly on developing commodity production, improving its circulation, achieving more production and marketing. We simply cannot count on any more price raises or lowering the base price for procurement base.

Finally, we must emphasize that peasants should make more contributions to our country. "When the level of the big river sinks, the small streams will be dry." [Individual well-being depends on collective prosperity.] We are a socialist country, and only when the country as a whole is prosperous can the peasants' livelihood be further improved. At present, our country has a policy of enriching the people, the peasants in return should be patriotic in their actions. The peasants of our entire province must establish for themselves the concept that the nation comes first, conscientiously follow the state's plans, guarantee the fulfillment of the state's procurement and purchase tasks, and strive to make even greater contributions to the state.

SOME TIPS ON PROPAGATION OF SEEDLINGS GIVEN

Fuzhou FUJIAN RIBAO in Chinese 23 Jan 82 p 1

[Article: "Agricultural Specialist Suggests Conscientious Attention to the Link Between Seedling Propagation and the 'Return of Spring Coldness' During Sowing Season This Year"]

[Text] Just before the [lunar] new year, the provincial Department of Agriculture convened an early rice seedling propagation symposium attended by specialists, scientists, and technicians concerned from the provincial Academy of Agricultural Sciences, from meteorological units, and from agriculture departments in Fuzhou Prefecture, who analyzed characteristics of sowing this spring and put forward very good suggestions about the propagation of seedlings for spring sowing.

The specialists felt there were several points about seedling propagation for spring sowing this year, compared with previous years that were deserving of serious attention. First was the poor weather. According to forecasts from meteorological units, climatic temperatures during spring sowing will likely be 1 or 2 degrees lower than in 1981. During the first 10 days, middle 10 days, and early part of the last 10 days of March, when everywhere most seedling planting is done, in most years, a "return of spring coldness" will likely occur twice, posing an extensive threat to the sowing of seeds and the growing of seedlings. Second, the seed quality is relatively poor this year. As a result of last year's severe "May cold" and the damage caused by rice blast disease, the quantity of fine variety seeds retained is everywhere inadequate. In addition, a large number of different places have exchanged seeds, and the purity of the varieties is inadequate. In some areas of rice blast disease, more than 10 percent of the seeds carry rice blast bacteria. Third, following the implementation in rural areas of various forms of production responsibility systems, countless households sow and grow seedlings in a decentralized way, and many peasant households do not understand or have not mastered well the techniques of propagation. The specialists suggested the following:

1. An intensification of leadership over spring sowing and seedling propagation work is genuinely needed. Sturdy seedlings are a crucial measure for increased paddy rice yields; this has historically been a weak

link in Fujian Province's paddy rice production, and all jurisdictions must give diligent attention to it.

2. The organization and management of seedling propagation must be taken in hand. They recommended that production teams select hands skilled in seedling propagation and organize specialized seedling propagation teams to carry out centralized propagation of seedlings of different varieties from fine variety seeds that peasant households turn over to them. Alternatively, neighboring households, acting under the principles of voluntary participation and mutual benefit, should go in for joint propagation of seedlings, or else old experienced peasants might serve in households specializing in seedling propagation, with the production team acting to organize them. In short, there should be an adaptation of general methods to local situations and there should be mass discussions, with various forms of responsibility systems adopted in order to achieve the goal of breeding sturdy seedlings. However, no matter the method used, matters must be taken firmly in hand and implemented about half a month before propagation of the seedlings.

3. Agricultural units and stations for the promotion of agricultural techniques in all counties and municipalities should enhance guidance of seedling propagation techniques. Right after the lunar new year, they should immediately organize forces centering on communes to operate training classes in the propagation of sturdy seedlings, and they should organize those skilled in seedling propagation to exchange experiences. During the period of seedling propagation, they should intensify traveling around to give technical guidance, emphasizing at the same time the timely sowing of seeds, and making sure that sowing is done when temperatures over a 10-day period average 12 degrees centigrade. There should be general promotion of the selection of choice seeds using salty muddy water, and the disinfecting of seeds by soaking them in "402" antibiotic solution. Damp seedling propagation and sparse sowing to propagate sturdy seedlings should be promoted.

4. All jurisdications should conscientiously inspect seeds for quantity and quality, and should diligently transfer seeds when an excess or a shortage is found.

ERRANT IDEOLOGY BLAMED FOR VEGETABLE SHORTAGES

Fuzhou FUJIAN RIBAO in Chinese 22 Feb 82 p 1

[Article by commentator: "Suburbs Should Make Vegetable Production Paramount"]

[Text] Having vegetables to eat is a big thing in the life of the people. Back in 1957, Comrade Chen Yun pointed out; "The significance of the problem of supplying vegetables and other foodstuffs is no less than that of factory construction, and it must be placed in a position of equal importance with the building of factories." In recent years, both the CCP Central Committee and the State Council have on several occasions issued instructions requiring that all cities and industrial and mining areas solve vegetable supply problems.

Thanks to the importance attached to it by party and government leaders at all levels, vegetable production and supply work in Fujian Province has scored definite achievements in recent years. To take Fuzhou as an example, in 1981 each person averaged 9.6 liang of vegetables daily, which compares favorably with the situation in 35 of the large and medium-size cities of the country. In 1981, Chinese cabbage, which formerly could be supplied only on holidays, continued to be supplied over a 4-month period. Prices for vegetables were kept virtually stable, but the supply situation varied from place to place. In many cities and towns, as well as in state-run shops in industrial and mining areas, vegetable supplies decreased. The state-owned supplies were insufficient, so vegetable prices in farmers' markets shot up, and the masses complained a great deal. Furthermore, quantities of vegetables delivered to market were uneven--sometimes a lot; sometimes a little. Varieties were uninteresting, and problems with tough vegetables that had grown for too long were serious.

The vegetable shortage in cities is partly the result of natural disasters, but it is mostly attributable to a series of problems existing in vegetable production and supply which have not been fundamentally solved. A program making vegetable production paramount in the agriculture of the close-in suburbs has not been genuinely put into effect. In terms of the province as a whole, the following three problems are the major ones requiring solution in vegetable production. First is providing areas for vegetable fields. An insufficiently large area for growing vegetables is a rather conspicuous problem in current vegetable production. According to statistics from provincial units concerned, in seven cities (Fuzhou, Xiamen, Zhangzhou, Quanzhou, Sanming, Longyan, and Nanping), and five counties (Yongan, Shaowu, Putian, Ningde, and Jianyang), the vegetable-eating population has increased annually for the past several years, but the vegetable-growing areas has decreased annually. Except for Fuzhou, where vegetable fields average a bit more than 3 li per capita, in other cities and counties it is less than 3 li, and less than 2 li in some. In other counties and cities, the problem of insufficient vegetable fields exists universally. Land is scarce and outputs are neither high nor consistent, producing a supply shortage. There are numerous reasons why the vegetable-growing area has declined, the most important being the excessive amount of land taken for urban construction and for commune and brigade enterprises. Construction of commune members' homes has also used a portion. Every year for the past 3 years in Fuzhou, almost 1,000 mu of established vegetable fields (amounting to the output from 3,000 mu of new vegetable fields) have been taken over. In Siamen and Sanming, about 400 mu have been taken away annually. There is no way to figure how much vegetable land has been taken by commune and brigade enterprises and by commune members for the building of houses. Strict control over the requisitioning of land and prohibition of arbitrary occupation of vegetable fields have become the urgent task of the moment in order to guarantee vegetable field areas for vegetable production. Recently, the provincial government promulgated new regulations on the requisitioning of vegetable fields, and all jurisdictions should conscientiously implement them. In terms of "deciding production on the basis of needs, production being slightly greater than marketing," the vegetable-growing area is inadequate and should be augmented to supply the population. All municipalities and counties should also set up special bases to supply routine vegetable needs and holiday vegetable needs that are farily concentrated in their area of distribution, that produce consistently high yields, and that are permanent.

Second, a sufficient work force in the vegetable production frontlines has to be assured. Today in suburban vegetable-growing communes and brigades, the general tendency is toward emphasis on industrial sideline production, with vegetable production being slighted. Many communes and brigades put their labor force and funds to work on development of industrial sideline occupations, thereby creating a labor shortage on the vegetable production frontlines. When some commune and brigade cadres do not grow vegetables but take the lead in industrial sideline occupations, the production enthusiasm on the part of commune members for the growing of vegetables is particularly impaired. There are many reasons for this situation, but the major one is that during the past several years, party organizations in these places have slackened ideological and political work among the vegetable-growing peasants. Following the institution of vegetable production responsibility systems, in particular, some cadres abandoned leadership. Consequently, among some suburban cadres and commune members an erroneous mentality grew up of no concern for the country and interest only in making money. They went for whatever they could earn money from, eating grain supplied by the country and not taking responsibility for growing vegetables, in a trend toward the free allocation of the work force. Unless action is taken to put a resolute stop to this, vegetable production cannot be carried out well. All jurisdictions should devote major efforts to intensifying ideological and political work among vegetable-growing peasants, launch indoctrination in socialism and patriotism, and, simultaneous with doing a good ideological and political job, formulate a body of regulations to stabilize work forces for vegetable production, submit to state plans, and grow sufficient quantities of good vegetables.

Third is the need to bolster leadership over vegetable work. Vegetable production, like other sectors of agricultural production, is a process of material production in which natural reproduction and economic reproduction are closely combined. The vegetable problem is a complex, interlocking problem that has ramifications in many areas. Leaders must take it firmly and surely in hand. In its notification concerning the strengthening of vegetable production and management work in large and medium-size cities and industrial and mining areas, the State Council also noted: "It will not do to devote attention to urban vegetable-production work for a short time only, nor will it do to relax attention for a time and tighten attention for a time." Today, numerous problems exist in vegetable work. Leaders everywhere must arouse their spirit and take action with full knowledge of the difficulties, genuinely strengthen leadership, and solve problems. We believe that only if leaders at all levels truly handle as a major problem the solving of the problem of vegetables for urban people to eat can the vegetable supply situation in the cities and the industrial and mining areas of Fujian Province be definitely improved.

MEASURES TO BOOST SPRING VEGETABLE PRODUCTION DETAILED

Fuzhou FUJIAN RIBAO in Chinese 22 Feb 82 p 1

[Article by Correspondent Xie Zuyi [6200 4371 5030]: "Exert Efforts To Make Sure Urban Residents Have Vegetables To Eat During Scarce Season; Fuzhou Municipality Convenes Vegetable Work Conference, Which Proposes Eight Measures"]

[Text] How can a sufficient quantity of vegetables of many varieties be assured for the people of Fuzhou during the spring of scarcity season? The work conference recently convened by the Fuzhou Municipal CCP Committee and municipal government proposed eight measures to be taken.

Difficulty in getting vegetables to eat during the season of spring scarcity is an old and difficulty problem. Since last October, the municipal CCP committee and municipal government have held several meetings to arrange for this year's vegetable production and to solve spring season scarcity problems. All vegetable-growing communes and brigades have also done much work. Throughout the city, more than 4,000 mu of cabbages are being grown to meet needs during the season of spring scarcities--something that has not happened for a good number of years. However, a recent check shows that because some work was not looked after as it should have been, and particularly because of the heavy migration to other places by work forces from the frontlines of vegetable production, during January between 500 and 600 mu fewer short-term vegetables were grown to get through the spring scarcity period, and now the management of vegetables needed to get through the spring scarcity is in some cases poor. If matters are not properly attended to, a shortage of vegetables will occur in markets from mid-March to mid-May.

The meeting conducted discussions of this situation. Leadership comrades attending the meeting from areas around the city, from suburbs, and from Minhou County, leadership comrades from 12 communes charged with responsibility in units under direct jurisdiction of the city expressed views. On the basis of conference discussions, the municipal CCP committee and the municipal government proposed eight measures to solve the problem of scarcities in spring production.

First, this year's vegetable production plans must be strictly carried out to make sure that the area planted to vegetables will not be a single mu short. Acting on the principle of "setting production according to needs, production being slightly greater than marketing," the municipal government handed down to surrounding areas, suburbs, and Minhou Country the areas to be planted in vegetables for the year in order to assure the supply to markets of 39 varieties totaling 2.2 million dan for the year. In order to ensure a smooth flow of vegetables to markets to get through the period of spring scarcity, the municipal government issued separate quotas to communes and brigades in each area and county for the daily arrival of 6,000 dan in markets. For the planting quotas not fulfilled for January, the municipality required supplemental plantings of sufficient kinds and quantities, as time permits.

Second, good care must be taken of available vegetables, particularly of the more than 4,000 mu of cabbages needed to get through the period of spring scarcity. The city decided to allocate an additional 100 tons of chemical fertilizer to communes and brigades to increase their fertilization, while at the same time doing a good job of getting urban nightsoil and garbage into the countryside.

Third, persevere in a program of "vegetables first, in the agricultural production of close-in suburban areas," with work forces that have gone elsewhere returning to grow vegetables. The municipal government required that for a short period of time, one worker per mu must be assured, and that one worker per 1.5 mu must be assured over the long run. Insufficiencies should be made up by transfers from industrial sideline occupations. If workers who left the growing of vegetables to go elsewhere do not return to the fields within 3 month's time, their grain rations will be cut off and they will have to eat grain bought at negotiated prices. While diligently doing a thorough, detailed ideological job, all communes and brigades are to formulate, on the basis of urban requirements, specific regulations for stabilizing the labor force. Commune and brigade cadres and party members should take the lead in growing vegetables.

Fourth, the Municipal Vegetable and Soysauce Company is to give strict attention to the signing of supply and marketing contracts with production units that reflect plans, including time for deliveries to market, quantities, quality, varieties, and prices. Industrial and commercial management organizations are to strictly supervise the carrying out of contracts by both producers and marketers, and those who do not carry out their contracts are to suffer economic penalities.

Fifth, in addition to the 1.15 million yuan formerly allocated by the municipal government to pay salaries and to help with the construction of old vegetable-growing bases, it has been decided to allocate an additional 1.15 million to help communes and brigades enlarge new vegetable bases and to install spray irrigation equipment in order to upgrade their ability to resist drought and achieve consistent, high yields.

Sixth, do a good job of distribution. The Municipal Vegetable and Soysauce Company is being required during the period of spring scarcity to do everything possible to assure the daily delivery of 300 dan of beansprouts and 10,000 jin of beaneurd to markets. There are also plans to buy 30,000 dan of vegetables from other places, and quantities of spring bamboo shoots, broad beans, and peas.

Seventh, intensify market management. During the period of spring scarcity, municipal industrial and commercial departments should intensify their patrols and checks in order to assure that vegetables are not sent out of the area. All communes and brigades should assure that vegetables grown under the plan do not find their way into the free markets. Violators are to pay a fivefold fine for each offense. Vegetable shops should not sell vegetables to profiteers or willfully transport them elsewhere for sale. Not only will violators have all such vegetables confiscated, but the head of the shop or the persons in charge will be fined 100 yuan.

Eighth, improve the organization of leadership. The municipal CCP committee and municipal government are requiring cadres at all levels to go into the frontlines of production to strengthen leadership over vegetable work. All cadres should exercise their responsibilities, and all units concerned should launch competitions to see who can make the greatest contribution to solving the problems of spring scarcity. Units or personnel that botch up or place obstacles in the way of vegetable production or supplies are to be investigated, and blame will be fixed.

Delegates to the conference unanimously praised and supported the municipal CCP committee's and municipal government's eight measures and indicated their intention to assure implementation of these measures and to study ways of solving scarcities in the fall. Surrounding areas are shouldering 80 percent of the production tasks for the city, and the head of the area, Jin Nengchou [6855 5174 4693] expressed, on behalf of cadres and commune members throughout the area, the intention to fulfill resolutely the task handed down by the municipal CCP committee and municipal government, and to make every effort to solve the spring scarcity problem in order to satisfy the needs of the people throughout the city for vegetables to eat.

FARM MACHINERY CONTRACT RESPONSIBILITIES OUTLINED

Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 1, 1982 p 5

[Article by Tao Fuxiang [7118 4395 4382] and Zhao Wenhai [6392 2429 3189], Farm Machinery Bureau, Tianshui Prefecture, Gansu Province: "Perfection of the Farm Machinery Contracting Responsibility System"]

[Text] In the process of establishing a responsibility system, for the contracting of farm machinery, inasmuch as neither party to the contracts has a knowledge of contracting, and since many management cadres lack a clear understanding of the new changes that have taken place in farm machinery work during the current readjustment period, and have not sufficiently studied the new circumstances and new problems, the following problems exist in varying degrees:

1. Contract duties lack a basis. Amounts of work are set inequitably, and there is a great gap between the high and low [figures] in contracted sums of money--the sums mostly being low--which enrich the individual and deplete the collective.

2. At the time of contracting, because of the use of unreasonable methods, such as the drawing of lots and abuses of authority by production team cadres, unlicensed operators (or new operators) are fairly common, and in some cases contracting is done with operators from other production teams or other communes.

3. More frequently than not, no long-range plans are made with regard to tractor drivers. Consequently, when time is about to run out, tractors are overworked, and a serious problem of changes in personnel to operate farm machinery exists.

4. Financial management is in quite a mess. Receipts and disbursements are not recorded, and receipts and bills are not kept. There are no accounts that can be checked to determine whether administration is good or bad, and it is impossible to carry out statistical work.

5. Because contract agreements have not been signed, are not in good order, or are not carried out strictly, the following has happened: Farm work is

not done, but rather people prefer to go outside their production team to engage in sideline occupations. Monies are not turned over to the collectives on time. After accidents involving machinery take place, there are mutual denials and failure to pay for economic losses. Operators "understand bonuses but not deductions," and there have been cases in which contracts have been torn up when earnings were not good or machinery was damaged. Seeing that operators have good earnings, production team cadres raise contract prices at whim. When major repairs are required, the collective does not want to take responsibility for major repair expenses.

In order to improve the farm machinery contracting responsibility system so as to make farm machinery better serve agricultural production and the masses livelihood, we believe that in the process of promoting farm machinery contracting responsibility systems, contract agreements have to be signed, and at the time of signing such agreements, consideration and attention should be given to the following "10 fixeds":

1. Fixed condition of vehicles: Units [should be] formed to appraise the condition of vehicles. These units [should be] composed of personnel in charge of machinery maintenance at commune farm machinery management stations, old operators, and production team cadres for the purpose of classifying machinery into three categories, on the basis of mechanical condition, for use in setting amounts of money for the contracting.

Category I vehicles: Includes newly purchased vehicles or vehicles that have undergone major overhaul, as well as vehicles in very good mechanical condition even though they have not undergone major overhaul (those that have "none of the three leaks," have "the four cleans," and have "the five goods.") Generally such vehicles are those that have been in service from 1 to 4 years and whose tires have 80 percent or more of their tread.

Category 2 vehicles: Includes vehicles that have been in service for 5-7 years; though they have undergone major overhaul, their tires have not been replaced or else have more than 60 percent of their tread remaining. Also included are those vehicles that, though they have been in service for 8 years, have had major parts and tires replaced (or are 80 percent new), and their mechanical condition is good.

Category 3 vehicles: Includes vehicles that have been in use for more than 8 years and which, though they have undergone major overhaul, have not had their tires replaced. Also includes vehicles whose parts are all in comparatively normal working condition, despite lack of major overhaul, and whose tires are better than 60 percent new.

Vehicles below category 3 require repairs before they can be contracted out. Those vehicles that are too costly to put into condition or that cannot be put into condition should be taken out of service or scrapped. Processing machinery used in the processing of agricultural sideline products should also be categorized according to their mechanical condition.

2. Fixed duties (amount of work)

(1) On the basis of the average gross income during the past 2 or 3 years, figured together with the local amount of income required to live, and depending on the mechanical condition of the machines, an equitable annual income from them should be set. Everything else being equal, a commensurately higher amount of work should be set for those machines that are in good mechanical condition.

(2) After experiments have been conducted, or on the basis of vehicle performance over the past several years, an overall analysis should be made of gasoline consumption, and a relatively equitable base figure should be set for gasoline consumption per standard mu (0.7 to 0.8 kilograms is about right), this base figure being used to figure the amount of work done by each category of machine each month or each quarter (or year).

3. Fixed percentage deduction: Machine operators are to be responsible for fuel expenses, day-to-day maintenance expenses, and wages, and collectives should deduct for major overhaul expenses, depreciation, public accumulations, and management expenses. Portions withheld by collectives should be applied as special funds to be used to help replace machines. Withholdings should be made according to the category of vehicle condition: For category 1 vehicles, withholdings may be 40 percent of gross earnings or cost per mu (12 percent for major overhaul, 12 percent for depreciation, and 16 percent for accumulation). For category 2 vehicles, 35 percent may be withheld (12 percent for major overhaul, 10 percent for depreciation, and 13 percent for accumulation). For category 3 vehicles, 30 percent may be withheld (10 percent each for major overhaul, depreciation, and accumulation).

4. Fixed operators:

(1) Only those operators who have undergone training and are licensed may be hired; unlicensed people may not be hired.

(2) Unlicensed personnel who have already been hired to operate machines must be tested within a limited period of time, the qualified being issued licenses and the unqualified unquestionably taken off [the machines].

(3) Priority should be given to the hiring of qualified operators from within one's own commune or brigade.

(4) Operators of machinery used in processing agricultural sideline products, as well as operators of diesel engines must also be trained and licensed under universally applicable appraisal criteria.

5. Fixed amount of farmland work. On the basis of the area that can be cultivated by machinery or the area that the masses want cultivated by machinery (including the grinding of grain, the hauling of manure, and similar farm work) following the fixing of output quotas on a household basis, and on the basis of the number of tractors ordinarily operating, horsepower should be apportioned to assure that priority is given to

agriculture. Standard fees for cultivation, using a gasoline-consumption figure of 0.8 kilogram per mu, would be 1 yuan per mu. If the gasoline-consumption figure was 1.6 kg, the fee would be 2 yuan, etc.

6. Fixed repair fees. Day-to-day maintenance fees are the responsibility of the operator, and responsibility for major overhauls (consideration given to tire replacement as well) are the responsibility of collectives, however stipulated.

7. Fixed safe production. Operators working under contract should strictly follow maintenance regulations, traffic rules, and operating procedures. When accidents occur, damage of under 100 yuan is the responsibility of the operator; damage of more than 100 yuan will be adjudicated by supervisory units (or public security units).

8. Fixed statistical reports: Contract operators must conscientiously keep a daily diary in which they record accounts, and promptly each month they must provide a factual report and figures to commune farm machinery management stations. Those who fail to make reports should be appropriately punished.

9. Fixed dates for handing over funds. Each month or each quarter, contract operators must turn over to collectives portions to be withheld from annual contract sums; they may not make one final settlement at year's end. Those who delay making payment or refuse to pay should be punished according to the seriousness of the circumstances.

10. Fixed handover. Files on mechanical condition of all farm machinery should gradually be built up. At the time of contracting, both parties should follow a handover procedure, including conscientiously filling out a record of handover and a contract agreement. At the end of the contract period, mechanical condition of machines and all implements that go with them should be complete. Except for ordinary wear and tear, all machine parts that have been damaged are the responsibility of contract operators to replace or repair, and tools that have been lost must be replaced.

The spirit of the foregoing 10 articles must be considered and clearly written down (or printed) as a part of the contract agreements. Supervisory and authenticating organizations may be either commune farm machinery management stations or production brigade management teams. Once an agreement has been made, it has the force of law, and no one may change or destroy it in an unauthorized or willful manner. All who destroy agreements shall be punished severely; required economic punishments are to be discussed by the masses.

BRIEFS

COMMUNE, BRIGADE ENTERPRISES--Commune and brigade enterprises in Guangdong Province have embarked on the work of processing materials supplied by foreign firms, assembling parts supplied by foreign firms, manufacturing goods as per sample supplied by foreign firms, on compensation trade, on cultivation and breeding for foreign firms and on cooperative management with foreign firms. Last year, they signed some 2,500 contracts of various kinds with foreign firms and earned D58 million of processing charges. The processing charges earned by commune and brigade enterprises in Foshan Prefecture in the first quarter of this year were 46 percent more than in the corresponding period of last year. [HK060625 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 29 Apr 82]

SUGAR REFINING--The sugarcane refining season has ended. Seven large sugar refineries at the Pearl River Delta in Guangdong Province are making use of this period of the suspension of refining to process imported unprocessed sugar for inland provinces and municipalities and to process unprocessed sugar supplied by foreign firms in order to earn processing charges. At present, they have been entrusted the task of processing 280,000 tons of unprocessed sugar. The province will fulfill its quota for processing 300,000 tons of unprocessed sugar for this year. [Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 29 Apr 82 HK]

BACKGROUND TO DEVELOPMENT OF TWO NEW CORN HYBRIDS GIVEN

Shijiazhuang HEBEI RIBAO in Chinese 21 Feb 82 p 3

[Article by Yi Lanfang [0122 5695 5364], agricultural technician, Beiyi Production Brigade, Fucheng County: "Breeding of Fine Varieties To Serve Agricultural Production"]

[Text] I have been a production brigade agricultural technician since 1966, and during the past 16 years I have introduced and test-planted a total of 43 parent pairs of hybrid corn and personally produced more than 160 hybrid corn combinations. As a result of the production of these combinations, experiments, and evaluations, four new bybrid combinations worthy of being promoted have been preliminarily bred, and two double-hybrid corn varieties of these have been extended to production. One of these used Zhengdan No 2 as the female parent and Hengdan No 7 as the male parent to produce a double-hybrid variety, which we named "Yishuang No 1." This variety has white kernels and and intermediate ripening. It shows fairly strong adaptability and resistance to disease. When sown in spring, it has a growing season of 110 days; when sown in summer, the growing season is about 100 days, making it suitable for intercropping in wheatfields. It has been currently extended to cultivation on more than 20,000 mu throughout the county. The second one used Tangdan No 14 as the female parent and Luyuandan No 4 as the male parent to produce a double-hybrid variety which we named "Yishuang No 2." This variety has short stems and ripens early. It has yellowish-white kernels and strong adaptability. Its growing season is from 85 to 90 days, making it suitable for sowing as a repeat corn crop. Last year it was extended to cultivation over more than 10,000 mu in the province. Under present circumstances, these two varieties will likely be further extended to cultivation, mainly for the following reasons:

1. Consistent and high yields. Because several single-hybrid varieties, all of which were varieties that had been extended to cultivation in fields, were used to produce the double-hybrid varieties, they were able to produce high and consistent yields. Results of comparisons made at 4 sites during the past 2 years showed maximum yields of 801 jin per mu and minimum yields of 608 jin per mu. At 3 sites, the yields were greater than from Zhengdan No 2 and Tangdan No 14. The degree of increase in the yields ranged from 1.1 percent to 14.6 percent.

2. High seed-production output. Low seed output from single-hybrid varieties of corn has been a universal problem in seed production work, but by using the double-hybrid variety method, the seed production process becomes an increased yield process. Consequently, it has effectively solved the problem of an overly large seed-production area and low seed-production output.

3. Good quality. Hyalin content of the seeds is high, and the masses report that it is wonderful for making porridge or for making dry grain.

4. Low seed cost, so it is welcomed by users. Output is low in seed production from single-hybrid varieties of corn, and costs are high. According to national price standards, 1 jin of seeds should exchange for between 2 and 3 jin of grain at from 1.30 to 0.40 yuan. Double-hybrid-variety seed production is high and costs are low, so generally 2 jin of grain are exchangeable for 1 jin of seeds, plus some slight subsidy.

What is the best way to produce seed corn? As a result of more than 10 years of experience, I have gained an understanding of the following several points:

First is the growing of seedlings in coldframes for added generation reproduction of parent pairs of corn-producing seeds, so as to shorten the breeding cycle. The cycle for agricultural production is fairly long. In the conventional breeding of corn, it takes 3 years from the introduction of inbred lines into reproduction until the production of hybrid seeds usable in production. If one wants to shorten the seed-production cycle, it is necessary to practice added generation reproduction. By so-called added generation reproduction is meant the use of scientific methods to proceed from the growing of one corn crop a year to realize two corn crops in the same year. To get added generation reproduction, the method formerly used was to go south to Hainan Island to do the breeding. During recent years, the method of using large plastic enclosures for reproduction has been developed. But the investment required for these methods is too great. We proceeded from the realities of our own situation to use the simple form of coldframes for progagation of seedlings in the early springtime, and we also instituted added generation reproduction of corn hybrid parent pairs. This has meant the propagation of corn seedlings during later February, with maturation occurring in either late June or early July; seeds from the harvest are used to plant a second crop of corn. This method, though simple, has expanded the corn reproduction coefficient and shortened the seed production cycle.

Second is the direction sowing of individual seeds for vastly increased reproduction. In order to do a good job of corn breeding, I asked for help from research units everywhere and was able to bring in more than 40 different kinds of hybrid parent materials. Quantities of seeds brought in ranged from as few as several kernels to as many as several tens of jin. I sowed them individually in holes for vastly increased reproduction, with the result that the seeds from elsewhere quickly put out roots in my soil.

Third is [the technique of] reproduction in bags to improve the purity of the seeds. Every year we carried out self-seeding by bag pollination on more than 600 individual plants of between wp and 30 corn varieties in order to maintain the improved variety characteristics and purity of hybrid parent pairs. Appraisals conducted 6 years after the introduction of the fine varieties shows purity still at 100 percent. Hybrids thus produced have strong hybrid heterosis and high quality.

TIPS ON SPRING CARE OF WINTER WHEAT IN DROUGHT CONDITIONS

Shijiazhuang HEBEI RIBAO inChinese 21 Feb 82 p 1

[Article: "Scientific Care of Wheat for a Bumper Summer Crop; Deputy Director of Provincial Department of Agriculture and Agronomist Gong Bangduo [7895 6721 6995] Express Views on This Spring's Wheat Care Issue"]

[Text] Recently, deputy director of the provincial Department of Agriculture, agronomist Gong Bangduo, expressed the views given below about how to take good care of wheat this spring in order to win a bumper summer harvest.

This year the wheat seedling situation in Hebei Province was poor before the arrival of freezing weather; there was good overwintering, and there was a good greening up in the spring. Specifically, because of the drought and low temperatures last fall, the reduced area sown, and the late sowing, there are a lot of third-grade wheat seedlings and little tillering. This is very disadvantageous for winning a bumper wheat harvest. Following the onset of winter, however, the situation took a turn for the better. First of all, this year's winter was warm and the climate favorable. So far there has been no killing freeze of seedlings. Second, care given during overwintering was good. The province's winter irrigation area consists of more than 20 million mu--a 13 percent increase over 1981--and this year the area irrigated was greater than in recent years. Third, except for Tangshan Prefecture, the wheatfields in most places remained substantially green throughout the winter, and in many irrigated places tillering increased during winter. Fourth, the frozen horizon of the soil was between 2 and 5 cun shallower than in most years. It is anticipated that spring will break the winter drought, and that it will not be necessary to replace many wheat seedlings. The slight consumption of soil fertility will help an early and a rapid greening up, the promotion of tillering, and an increase in the number of spikes. As long as care is increased, there is still hope of winning a bumper harvest.

Spring care of the wheat this year will require making sure that plant colonies are small and that there are a lot of seedlings late in the season. With regard to the major problem of dry weather, the focus will have to be on "two increases and two protections"; i.e., increases in tillering and in heading, and protection against spring freeze and spring drought. Advantage should be taken of the continued greeness of this year's wheat during overwintering, and of the early greening up, to initiate action early, get to work early, and care for the wheat early in order to promote its growth--taking into account differences in the condition of seedlings and the soil moisture conditions to tailor and adapt general methods to local situations in order to give attention to the following crucial measures:

First, there is a need to combat drought so as to preserve the moisture of the soil, and to guard against freezing to protect the seedlings. The drought situation still continues, and according to measurements taken at various places, the water content of the cultivated horizon of dryland wheat soil has fallen to an overall 5-10 percent. For wetlands wheatfields that were not irrigated during the winter, it has declined to 8-15 percent. For fields where no followup care was given following irrigation, the soil has hardened and cracked, and the loss of soil moisture is serious. Some 13 million mu of the province lack soil moisture. In addition, the winter is not yet over, and the return of spring cold could still occur. The wheat seedlings are still in danger of being killed, and there positively can be no lowering of the guard or carelessness about this. On the basis of experiences in various areas, measures to combat drought and guard against freezing in early spring consist mainly of the adaptation to local areas of the general methods of rolling, raking, and hoeing. Now is the time to take advantage of the icy conditions to act quickly. Depending on different circumstances, rolling primarily should be done on clay soils, on hardened soils that have cracked, and on wheatfields where the underlying soil moisture is good but the surface soil moisture is not good. For fields in which soil mositure conditions are good and for highly alkaline fields, hoeing should be primary. In addition to the hoeing, raking, and rolling of the wheat, as the weather gradually warms up, will clean away the soil around the seedlings in those wheatfields where seeds were planted too deeply or which were covered for overwintering. Where seeding was too shallow, the soil should be mounded up around the roots to prevent freezing and to protect the seedlings.

Second, localities should adapt general methods to their own situations, watering to help the greening of the seedlings. Watering to bring greening is very much dependent on proper technique, and the lessons of years of experience are numerous. Therefore, it is definitely necessary to emphasize scientific [methods]. On the basis of experiences in various places, the three looks, three earlys, and three lates should be taken in hand. By this is meant: look at soil moisture conditions, provide early watering where the soil moisture condition is poor, and water later where the soil moisture condition is fairly good. In view of this year's drought watering of the fields should begin early. Where there is a serious soil moisture deficiency (water content of the soil lower than 10 percent), or where the frozen horizon is very slight, now is the time to water with "lifesaving water." For wheatfields where soil moisture conditions are generally poor (water content of less than 17 percent for clay soils, less than 15 percent for a mixture of clay and sandy soil, and less than 13 percent for sandy soil) and where the frozen layer has melted, watering may be done. Look at seedling conditions: Generally speaking, early watering should be given to first- and second-category seedlings, and later watering given to late and weak seedlings. Look at conditions: In places where the ability to fight drought is not strong or where there is a long watering cycle, action should be taken early and the initiative seized so that most wheatfields will be watered within a proper period of time. The forementioned three points should be organically combined.

Third is a need for heavy fertilization for greening up. Except for individual high-yield fields, the number of plant colonies in most fields is insufficient this year, making a top dressing of fertilizer for greening up particularly important. Emphasis should generally be placed on fertilization that uses a combination of manure and water, and attention should be given to a combination of nitrogenous and phosphate fertilizers. Applying fertilizer before all the ice has melted should be done deeply, and under conditions of sufficient soil moisture, in order to prevent blind and wasteful fertilization.

Fourth, good care should be given to late and weak seedlings. This year there is a large area of weak and late seedlings, and special attention should be given to scientific care. Generally, roots are poorly developed in fields having late and weak seedlings, so early watering can easily result in chilling of the ground and no emergence of seedlings, or to the growth of seedlings that remain small even when they are mature, frequently bringing about just the opposite of the desired affect. For these fields, mostly the hoeing, raking, and rolling of the wheat should be done in early spring to increase warmth and preserve soil moisture, awaiting the growth of new roots before watering or fertilizing.

The key to good care of the wheat is the strengthening of leadership. Right now the wheat is steadily greening up, so it is suggested that all levels of CCP committees and government devote earnest attention to these tasks. Agricultural units at all levels should rapidly organize scientific and technical personnel to launch a campaign of two checks: check seedlings conditions, and check soil moisture conditions--adapting general methods to specific locales to propose measure for caring for the wheat in different kinds of areas, and acting as staff officers for the leaders.

In many places, systems of responsibility for wheatfield care are not in very good shape, and in some places they have not been established at all. Because there is no responsibility system, some pump wells have not yet been fully utilized. This is extremely detrimental to good wheat care. Therefore, while improving production responsibility systems, all jurisdictions should rapidly set up and perfect wheat care responsibility systems. They should do a particularly good job of various forms of specialized contracting for pump wells, and they should both arouse the enthusiasm of commune members for production and make the most of the superiority of collective production.

Attention should be devoted to watering the fields and to those wheatfields that produce intermediate yields. During this year's drought, full use should be made of irrigated wheatfields. The whole province should emphasize attention to the 20 million mu for which irrigation can be guaranteed, giving particular attention to the wheatfields among them that produce intermediate yields. Generally speaking, these fields should be watered three or four times or more, and fields that produce intermediate yields should be given proper attention for fertilization as well, so that yields ranging from 350 to 400 jin per mu will be possible. For wheatfields where water-conservancy conditions are poor, and for dryland wheatfields, the masses should be aroused to sink "happy old man" wells, combine the flow of many wells, and repair leaks in ditches, using every possible means to expand the irrigated area in an effort to harvest a little bit more.

Inform the many households of techniques for increasing yields. Following the institution of responsibility systems, the broad masses of peasants have urgently demanded science and technology. All levels of agricultural-research and technology-promotion units should seize the opportunity to rapidly organize large groups of scientific and technical personnel to give publicity to technology, to print and disseminate technical materials, to set up technical information stations, to test-run contract systems linking technology to output, and to make full use of various forms such as newspapers, broadcasts, and blackboard reports for the vigorous teaching of wheat technology.

GREATER DIVERSIFICATION OF CROPS EXPLAINED

Shijiazhuang HEBEI RIBAO in Chinese 9 Feb 82 p 1

[Article by Wang Guoqiang [3769 0948 1730]: "Ba County Readjusts Structure of Agriculture and Expands Economic Diversification as Result of Application of Agricultural Resources Survey and Agricultural Zoning"]

[Text] Ba County has applied results of agricultural resources survey and agricultural zoning to readjustment of the structure of agricultural production and to give scientific guidance to agricultural production to gain distinct benefits.

Ba County began a survey of agricultural resources and work on agricultural zoning in early 1980. As a result of the resources survey, the county was able to summarize its advantages and disadvantages in agricultural production and put forward more than 80 sensible suggestions for agricultural production. The County CCP Committee and the County People's Government used results of the resources survey to make the most of strengths and downplay weaknesses for readjustment of the structure of the agricultural economy and expansion of the ratio of economic diversification. While assuring grain production, it set a program of "longterm attention to forestry, intense attention to reeds, and attention to melons and vegetables for current year income." In 1981 the county grew 12,000 mu of Chinese cabbage alone, selling 27 million jin of it in Beijing and Tianjin for earnings of 1.8 million yuan. In 1981 county earnings from vegetables alone were 9 million yuan. Economic diversification in the county realized earnings of 31 million yuan in 1981, a 51 percent increase over 1979. They also made use of proximity to Tianjin and Beijing, and turned to advantage the county's more than 3,000 skilled craftsmen in vigorous development of commune and brigade industrial sideline occupations. Gross output value for all of 1981 reached more than 88 million yuan, a 10 percent increase over the previous year and a 52 percent increase over 1979. The plaiting of mats in the county's reed growing area last year earned the county 6 million yuan.

The county used results of its resources survey to restructure the farming system and readjust the ratios of summer and fall crops. Looked at in terms of quantity of heat, water resources, and soil fertility, this county has more heat than it needs for "one crop a year," and insufficient heat for "two crops a year," but for "three crops every two years," a multiple cropping index of 145 percent can be handled. On the basis of this data, Ba County began in 1980 to gradually cut back its wheatfield area. By 1981, the wheat growing area in the county had been reduced from the former

490,000 mu to 400,000 mu. Inasmuch as the county's light, heat and water conditions were suited rather well to the growing of spring corn, the spring corn acreage was expanded, with an additional more than 30,000 mu grown in 1981. This changed a situation of many years standing whereby grain production was increased in summer and decreased in autumn. In 1980 gross output of autumn grain increased by 74 percent over the previous year, with gross output of grain for the year showing an increase of more than 20 million jin over the previous year. In 1981, in a situation of severe drought, grain output still totaled 270 million jin, or the same as the year before.

Corresponding readjustments were also made in crop patterns on the basis of the resources survey. Ba County has 11 soil layers and 36 different kinds of soil, but formerly grain was invariably grown and resources were not used well. The county has more than 240,000 mu of sandy soil, which is rather infertile and porous to water and fertilizer. It is suitable for the growing of sweet potatoes and peanuts. On the basis of agricultural zoning, in 1981 the county readjusted the ratio of grain crops, expanded by 19,000 mu the growing of oil-bearing crops, and expanded the growing of melons and vegetables. As a result of this readjustment, advantages were preliminarily brought into play and economic benefits increased. Simultaneously with development of economic diversification, they worked hard at intensive growing of grain to raise per unit yields and maintain total output. In 1981, despite the growing of 50,000 mu less wheat in the county, total output remained what it had been in 1980, and total grain output for the county increased for two consecutive years as compared with output before readjustment.

Application of survey results to water conservancy construction changed the former emphasis on storage and slighting of drainage, and the emphasis on water in deep layers of the earth while slighting water in shallow layers. A combination of deep wells and medium-shallow wells were sunk, and pump well construction was combined with deep ditch waterway networks. In 1981, the county sank a total of 547 wells, 524 of which were medium-shallow wells. It also sank more than 6,000 bricked-up wells and earth wells, and dug more than 300 waterways. The county has also put into operation 551 spray irrigation devices to play a role in the struggle against drought. Some communes and brigades have also used the soil survey results to change the emphasis on ammonia while slighting phosphate fertilizer for scientific fertilization.

Postscript

Good agricultural resources surveys and agricultural zoning hold major significance for development of agricultural production. For a long time, as a result of the influence of "leftism," many places have not considered local peculiarities in guiding agricultural production. Regardless of the natural environment or climatic characteristics, they followed the same models, being subjectively one-sided, and giving blind guidance, thereby causing much hardship for the peasants and severe losses for the country. This lesson is a serious one.

In order to do a good job of agricultural production in an area, it is necessary to understand the local natural resources as well as historical, technical and social conditions, taking action on the basis of these realities and in accordance with natural laws and economic laws. Consequently, all jurisdictions must strive to make good surveys of natural resources for use in agriculture and do good zoning work, applying the results as quickly as possible to actual production, using the minimum amount of investment of funds to derive the maximum economic benefits.

CROP PATTERNS CONSISTENT WITH CYCLICAL CLIMATIC CHARACTERISTICS PROPOSED

Shijiazhuang HEBFI RIBAO in Chinese 11 Feb 82 p 2

[Article by Zhu Zhijian [4281 1807 0313], assistant engineer, Provincial Meteorological Bureau: "A Look at Agricultural Crop Patterns in Terms of Hebei Province's Drought and Waterlogging"]

[Text] In Hebei Province, drought and waterlogging disasters are rather serious, some areas having them virtually every year. The basic conditions producing drought and waterlogging are the effects of monsoon winds, great changes in the rate of precipitation, and uneven distribution of rainy seasons. Abnormal changes in atmospheric circulation are major factors producing great drought or great waterlogging. Destruction of ground cover on Taihang Mountain is also an element in the frequency of drought and waterlogging disasters.

Drought and waterlogging disasters in Hebei Province have four characteristics. One is their continuousness, i.e., continuous drought or continuous waterlogging. In Luancheng County, for example, in a period of 505 years waterlogging 2 years in a row occurred 40 times, and 3 years in a row 19 times. The longest consecutive period of waterlogging was 7 years. Drought for 2 years in a row occurred 39 times, and 3 years in a row 17 times, the longest drought lasting 7 years. Looked at in terms of the province as a whole, both the four particularly severe droughts that occurred between 1470 and 1840 and the two particularly severe droughts that occurred between 1840 and 1949 lasted from two to four years. Second is the alternation, i.e., the alternation of drought, waterlogging and ordinary years. Over a period of 505 years in Luancheng County, for example, an alternation of drought, ordinary and waterlogging years occurred a total of 293 times, for a 58 percent probability. Third is suddenness. Frequently in the course of a night or following one or two torrential rains, a fight against drought turns into the draining of waterlogging. In mid-July 1978 in Zunhua County, for example, only 60 millimeters of rainfall fell, causing a "stifling drought." By late July, however, the quantity of rainfall increased to 559.3 millimeters to bring disaster of another kind. This suddenness causes very great damage to agricultural production. Fourth is the cyclical nature. Drought and waterlogging are meteorological disasters on a large scale; consequently, their cyclical nature is rather obvious. Looked at in terms of the laws of evolution of Hebei Province's summer droughts, severe summer droughts over a large area occurred about once every 10 years. The same is true of waterlogging. In Hebei Province, the evolutionary law is one small waterlogging every three years, and one large waterlogging every seven years. In years of widespread, large amounts of rainfall, the waterlogged area tends to be on plains at the foothills of mountains, and in years of scant rainfall, the waterlogged region appears in coastal areas.

Because of the frequency of drought and waterlogging in Hebei Province, the agricultural climatic conditions causing inconsistent yield are rather conspicuous; therefore, crop patterns should not be overly centralized. This is because the more regionalized or specialized agricultural production is, the more severe are the demands on agricultural climatic conditions. Consequently, planting methods of regionalized or specialized crop patterns should not be adopted for use in Hebei Province. All that can be done is to proceed from full and equitable use of climatic resources to adapt general methods to local conditions, centralize appropriately, match early and late ripening varieties of crops, match summer and fall ripening crops , plant a mixture of different crop varieties, and take the path of comprehensive development of farming, forestry and animal husbandry. In addition, crops that are fairly tolerant of drought, such as corn, millet and cotton, should be grown more.

Furthermore, multiple actions to control drought and waterlogging should be taken, curing the problem at its source. Major efforts should be directed to curing the problem at its source in Taihang Mountain by doing such things as solving the plant cover problem there, which would play a major role in reducing drought and waterlogging damage. On the plains, vigorous planting of trees for afforestation should be done to regulate the climate and moderate the disadvantageous conditions of frequent drought and waterlogging in Hebei Province.

BRIEFS

RECORD HOG PROCUREMENT--In 1979, live hog procurement in Hebei Province amounted to more than 4,838,000 head, more than 1,396,000 head more than in 1978, for a 40 percent increase. In 1980, procurement in the province amounted to more than 5,483,000 head, more than 644,000 more than were procured in 1979, for a 13 percent increase, marking an all-time high level for hog procurement in Hebei Province since the founding of the PRC. In 1981, procurement in the province amounted to 5,797,900 head, more than 314,000 more than in 1980, for an increase of almost 6 percent, again registering a new all-time high record. BRIEFS

RAINFALL 1-4 MAY--Rain fell in most parts of Heilongjiang Province from 1 to 4 May with the western and northern parts receiving more rainfall than the eastern and middle parts. Longjiang, Gannan, Tailai and Fuyu Counties and Qiqihar Municipalities had rainfall ranging from 57 to 20 millimeters. Precipitation in the northern part of Heihe Prefecture and the western part of Nenjiang ranged from 19 to 12 millimeters. Most of the remaining areas had rainfall under 10 millimeters. Soil moisture in most of the province is adequate thanks to this rainfall. Drought in the southern part of Nenjiang Prefecture and the southwestern part of Suihua Prefecture is somewhat relieved. The rainfall is conducive to sowing field crops and emergence of wheat seedlings. Waterlogging in the eastern aprt of Heijiang Prefecture worsened. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 4 May 82 SK]

FISH FARMING--Heilongjiang Province plans to invest 6 million to help communes and brigades develop fishing farming. Recent years have seen rapid development of freshwater fish-farming in the province. By the end of 1981, there were 2,400 fish-farming units run by communes and brigades in 69 municipalities and counties. Water areas for fish-farming totaled 1.64 million mu. The province plans to expand water areas for fish-farming to 2.25 million mu this year. [SK060633 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 4 May 82]

EXCESSIVE GROWING OF TOBACCO DISCOURAGED

Beijing ZHONGGUO NONGMIN BAO in Chinese 21 Feb 82 p 2

[Article by Wang Biao [3769 1753]: "Blind Growing of Tobacco Must Give Rise to Bad Consequences"]

[Text] Henan Province is a major tobacco base for the country, both area planted and total output amounting to one-third the national total. In 1981 plans called for Henan to grow 1.7 million mu, but 2.3 million mu was actually grown for an output of 750 million jin. A person in charge at the Henan Tobacco Institute told the reporter that "comrades in charge in the central government have already directed that national tobacco acreage this year not exceed 8 million mu. A survey shows that this year the tobacco growing area in Henan will be expanded to 4.7 million mu, or may even break the 5 million mu mark." Such blind development of tobacco must give rise to bad consequences. First is stockpiling and waste. Such a lesson has already occurred several times in history. In 1979, Henan expanded tobacco growing and had a bumper autumn harvest giving rise to stockpiling and waste. The tobacco leaf could not be burned, nor could it be composted. Bank loans to buy tobacco and store it in warehouses cost several tens of thousands of yuan per month in interest alone. Quite a few communes and brigades in Xiping County composted the tobacco, but the following year many crops caught communicable diseases. If 4.7 million mu is grown this year, figuring a yield of 300 jin per mu, that means 1.41 billion jin. Exporting it will not work; it will have to be marketed helter-skelter domestically, causing disruption to the state plan. Second is decline in quality. Comrades at the Henan Tobacco Institute said that during the 1950's Xuchang tobacco enjoyed a very high reputation in international markets, and all countries were anxious to buy it. Since 1970, however, as a result of one-sided pursuit of quantity, quality has increasingly declined, and it has lost its competitiveness on international markets occasioning great losses for China. Third is the creation of management turmoil. In Henan, 11 large tobacco plants have been approved the state. Some of the small tobacco plants that were shut down by State Council directive in 1979 have not only resumed operation, but a large number of small rustic workshops operated by individual households have started up. These small tobacco plants and small workshops evade taxes and cheat on taxes, raise tobacco prices as they please, and compete with large plants for raw materials. Some of them even collude with people in printing plants and in large tobacco plants to put out counterfeit products. In 1981, the Xuchang Municipal Control Comission discovered that a small family workshop had counterfeited Shanghai

"Daqianmen" brand and Xuchang "Daqianmen" brand, customers being cheated. To smoke this tobacco, one had to "get a high flame, shield it from the wind, and not greet any acquaintance one might meet (or the tobacco might go out in the time required to greet him), producing a bad effect. The comrade in charge of the Henan Tobacco Institute emphasized that blind development of tobacco production was taking place not only in Henan, but also in some northwestern and northeastern provinces. Consideration of the overall domestic and international market situation requires that the tobacco growing area be stabilized and quality improved to assure implementation of state growing plans. Actions that show no concern for state planting plans in a one-sided pursuit of increases in local financial earnings hurt both the country and the people, and should be corrected.

BRIEFS

RAPESEED HARVEST--Fengcheng and Dongxiang counties in Jiangxi have reaped bumper harvests of rapeseed this year. Fengcheng County's total output exceeds 6.79 million jin, an increase of 1.61 million jin over the all-time record last year. Dongxiang County's total output is 10 percent more than the record year of 1981. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 9 May 82 OW]

COTTON MEETING--A provincial meeting on cotton crop management was held from 28 to 30 April in Fengcheng County, Jiangxi Province. It was presided over by Liu Junxiu, secretary of the provincial CCP committee. It was pointed out at the meeting that, up to 25 April, a total of 1.41 million mu of cotton had been sown in the province, topping that at the same time of last year by 330,000 mu. The meeting urged cotton growers in the province to continue their good work so as to fulfill the cotton-sowing plan. The meeting also asked them to make every effort to strengthen the management of their cotton fields so that a bumper harvest will be achieved this year. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 3 May 82 OW]

CSO: 4007/407

BRIEFS

SOWING MECHANIZATION--Jilin Province has scored great achievements in mechanizing sowing operation this year. The province has sowed 16.21 million mu of crops by machines, an 880,000 mu increase over the 1981 figure. By 15 April, the province mechanically sowed over 1 million mu of wheat, oil-bearing seeds and beets, reaching 10 percent of its 1982 sowing plan for this regard. Over 40,000 large and small tractors throughout the province have been checked or repaired and are ready to engage in sowing field crops. [SK190612 Changchun Jilin Provincial Service in Mandarin 2200 GMT 18 Apr 82]

IRRIGATION CANAL--The 25 Li Long (Sanhe) irrigation canal was built and put into operation on 28 April in Jilin Province's Yanji County. (Sanhe) commune is located near Tumenjiang River. To channel the water of this river to irrigate paddy fields, the commune began the construction of this irrigation canal 5 February 1976. With this canal, 4 brigades and 14 production teams will benefit, and 15 million more mu of paddy fields can be cultivated. [SK041302 Changchun Jilin Provincial Service in Mandarin 2200 GMT 3 May 82]

GRAIN OUTPUT, RURAL INCOME INCREASE URGED

Shenyang LIAONING RIBAO in Chinese 18 Feb 82 p 2

[Article by Sun Weiben [1327 4850 2609], Tieling Prefecture Party Committee secretary: "Steadily Raise Grain Production and Greatly Increase Commune Member Income"]

[Text] Summary. In Tieling Prefecture, the average annual increase in grain output was 400 million jin for the past 4 years. This year the grain output is expected to maintain a steady speed of development. The main emphasis of grain production should be placed on the intermediate-state production brigades, approximately 65 percent of all brigades. Moreover, the potentials of the prefecture's five hilly areas and one water area [in contrast to four parts arable areas] should be explored for breakthroughs, and in the three areas of diversified economy, commune and brigade enterprises, and reduction of expenses. Thus, the income of commune members can grow at a faster pace.

Since the conclusion of the 3d Plenary Session of the 11th Party Central Committee, the Tieling Prefecture had bumper harvests 4 years in a row with an annual increase in grain output of about 400 million jin. The total grain output in 1981 was 4,820 million jin, a gain of 410 million jin over 1980 with a growth rate of 9.1 percent. Commercial grain sold to the state by the prefecture was 2,260 million jin; this averaged 770 jin per member of the agricultural population. At such a relatively high level, how can we continue to keep pace in grain output this year?

Concerning this problem, the party prefecture committee completed a comprehensive analysis of grain output for the entire prefecture: there are a total of more than 12,000 production brigades in the prefecture and 20 percent of them have relatively high production levels. These brigades have high collective outputs; cadres' management levels are also high because they earned the confidence from the masses. Given normal conditions, this year's grain output will not be decreased. However, 15 percent of the production brigades have relatively low production levels. These brigades have had low grain outputs, small [grain] reserves, high outside debts, and have long endured the practice of "sharing one pot of cooked rice." Both cadres and masses urgently demanded that the present situation be changed, and that a production responsibility system of linking remuneration to output be established so that 1982's grain output would increase to a relatively large extent. Standing between these two extremes are 65 percent of the production brigades with medium grain output, whose grain output is insufficient when compared to high level production brigades but more than sufficient when compared to the low production level brigades. These brigades have great potential since they make the decisive difference in grain output for the entire prefecture. It so happens that in this 65 percent of the production brigades, a rather large number of the cadres are hesitant about setting up the production responsibility system. Therefore, the prefecture party committee decided to place this year's work emphasis on these intermediate-state production brigades; cadres of these brigades must be helped to clear the ideological barriers to implementing the responsibility system and to know that the main criterion in distinguishing good or bad policy is whether it is helpful in boosting production and increasing income and that the main dividing line between socialism and capitalism is who owns the means of production and adheres to the principle "to each according to his work," and whether there is any exploitation. The party committee of the prefecture also helped cadres to look at production not just on simple terms, i.e., whether the labor is collective or individual, whether we should focus on collective management or individual management, or whether accounting units should be large or small. Moreover, the cadres of these intermediate-state production brigades should be helped to exert greater efforts to learn and study the responsibility system, and to actively carry out the guiding work well. Thus, the responsibility system can adapt to the local production level, and also to the awareness level of commune members. They were also helped to correctly handle the relationship between control and contract operations, enabling them to develop the superiority of collective economy and to mobilize the individual enthusiasm of commune members.

Of course, the rate of increase in grain output is determined by a number of factors and there are many aspects of work to be done. However, the central problem of higher grain output is to do well in these intermediate-state production brigades, especially in improving production responsibility system of these brigades.

As we work hard for a continual and steady growth of grain output, we must also speed up the increase of commune members' income. In Tieling Prefecture, there are five hilly areas, one water area, and four arable areas. It is apparent that we cannot live on four arable areas alone. This year we must make full use of local resources and local advantages to vigorously work on the the following three aspects on the basis of the overall development of forestry, animal husbandry, sideline enterprises, and fishery:

1. Seek Breakthrough in Diversified Economy

We should effect a breakthrough in the areas of "two silkworm species, two fruit species, one species each of sheep and rabbit," in order to mobilize a speedy development in diversified economy, because these activities need only small investments but yield rapid results. In the prefecture, there are barren hills, wasteland areas covered with plant stalks, and sizable grasslands; good conditions to develop tussah and mulberry silkworms, Chinese hawthorne trees, grapes and raise sheep and goats and rabbits. These activities can be quickly developed throughout the prefecture if only cadres at different levels can pay attention to diversified economy in the same way that they paid attention to grain. Early last year there were only 170,000 hawthorne trees in Xifeng County; but because the leadership of the three levels of county, commune and brigade had paid attention to diversified economy, the number of hawthorne trees increased to 810,000. In only a little over 2 years, the Xibeitu Production Brigade of Liushutun Commune in Kangping County tripled the number of sheep and goats.

II. Commune- and Brigade-Operated Enterprises Must Achieve Breakthroughs

In 1981, the gross output value of commune- and brigade-operated enterprises in the entire prefecture was approximaely 200 million yuan and the profit, less than 40 million yuan, was lower than that of the single county of Haicheng. This year the commune- and brigade-operated enterprises should gear themselves to the needs of the broad rural market. For example, it is projected that this year 70,000 houses will be built in rural areas in the prefecture. If the commune- and brigade-operated enterprises can mass produce bricks, tiles, cement, steel windows, terrazzo tiles, prefabricated pieces, and other construction materials, the enterprises concerned would not only have no worries about the source of raw materials, but also about the marketability of their products. This would be one way to accumulate wealth. Also, the agricultural and sideline products of Tieling Prefecture are quite abundant. Therefore, sound management of the initial and intermediate processing of agricultural, forestry, animal husbandry, sideline and fishery products also provides a way of wealth accumulation.

III. There Must Be a Breakthrough in Lowering Expenses

In recent years, production costs of the Tieling Prefecture hovered consistently near the 40 percent mark. There are two main reasons for the overly high production costs: one reason is that most production brigades irrationally applied chemical fertilizer without noticing the rational compounding ratios of nitrogen, phosphorus and potassium. As a result, costs were not reduced but the expected results of increasing output were not forthcoming. The other reason is that most production brigades illegally, in the name of the two items of "other expenditures" and "other grain reserve" bartered with others, feated and engaged in heavy drinking, invited guests and presented gifts. This year we must stress the scientific application of chemical fertilizers and eliminate the waste in the "two other" category, and make efforts to bring down the production costs.

COLD CLIMATE CORN, MILLET, SOYBEAN VARIETIES BRED

Changchun NONGCUN KEXUE SHIYAN [RURAL SCIENTIFIC EXPERIMENTS] in Chinese No 1, 1982 p 13

[Article by Zhang Guishan [1728 6311 1472] and Hu Jiahai [5170 0502 3189]: "Several New Varieties Suited to Mountain and Semi-Mountain Areas"]

[Text] Technicians at the agricultural science experimental station of the Dunhua County stock farm have bred, after several years of practice, several early maturing high yield new varieties with strong adaptability for high and cold mountain regions with a short frost-free period and slight effective accumulated temperatures. Some of them the province has evaluated as fine varieties, and Dunhua County has grown them over wide areas. Some other counties and communes are introducing and spreading their cultivation. In order to better understand and master these new varieties, a briefing on their characteristics is given below:

"Dundan No 2" Corn

The province has evaluated Dundan No 2 as a fine variety. It is a single hybrid corn bred in 1974 from the crossing of Pi 383, its female parent, with Liu 1-2, its male parent. It has a 112-day growing period and requires accumulated temperatures of 2,050°C. This variety has long, narrow leaves, a plant height of about 210 millimeters, strong stems that are resistant to lodging, and strong resistance to leaf spot. Young seedling leaf color is dark green, and growth is rapid. Kernels are of the semident type, their color being reddish yellow, and their per hundred weight 29 to 30 grams. A mu will support between 3,000 and 3,600 plants for an output of between 550 and 650 jin.

"Dunga No 4" Millet

The province has evaluated Dungu No 1 as a fine variety. It was bred in 1973 using intermediate line [0022 4842 4762] "large coarse head" seeds. It has a 100-105-day growing season and requires accumulated temperatures of from 1,800 to 1,900°C. It is strongly resistant to cold during the seedling stage and grows rapidly. Leaf tips are purplish. There is no tillering. Plant heights reach 120 to 130 millimeters. Stems are hard and thick, resistant to lodging. It is resistant to blast disease, white fungus disease, and yellow rust. Heads are ovular in shape and between 20 and 23 millimeters long. Head weight runs from 10.4 to 10.8 grams, and the per thousand weight of grains is 1.9 to 2.4 grams. Weight following removal of husks is 75 to 80 percent of gross weight. Yields are about 400 jin per mu. It is a variety that produces bumper grain yields and prodigious amounts of straw.

"Dunliang No 4" Soybeans

Dunliang No 4 tested out as a relatively fine variety in combined area experiments on soybeans conducted in the province, and it is currently being propagated over a wide area. This variety began in 1972 with the crossing of the female parent, "Fengshou No 13" with the male parent, "Xinsilihuang." It has a growing period of about 110 days and requires accumulated temperatures of about 2,000°C. Growth during the seedling stage is rapid. Leaf color is dark green; leaves are oval in shape; plant heights are about 70 millimeters, and it is characterized by limited pod formation. Many pods contain three or four beans. When pods are ripe, they are brown, and beans are cream colored or dark brown. The per hundred weight of beans is about 22 grams. Each mu supports about 15,000 to 16,000 plants for yields of 350 to 390 jin, making it a new variety with strong bumper yield characteristics.

LIMITATIONS ON SELF-DETERMINATION IN PLANNED ECONOMY STRESSED

Shenyang LIAONING RIBAO in Chinese 12 Feb 82 p 1

[Articulture by Commentator: "Continued Need to Take Planned Economy as Key Link in Agriculture"]

[Text] At the start of this new year [lunar calendar], Comrade Chen Yun invited comrades from the State Planning Commission for a discussion that emphasized adherence to taking the planned economy as the key link and market regulation as supplementary. He pointed out that ours is a planned economy in which industry takes a planned economy as the key link and that following institution of systems of responsibility in agriculture, it would still be necessary to take a planned economy as the key link. This is an extremely important fundamental policy in the building of socialism. Profound understanding of this fundamental policy and resolute implementation of this fundamental policy in this year's formulation of agricultural production plans is a major task facing the broad masses of cadres and commune members on the agricultural front.

"Since rural villages have universally instituted systems of responsibility, what is the point in emphasizing planned economy as the key link?" is the question that some comrades pose. This is to confuse systems of responsibility with planned economy. Systems of responsibility are an administration and management tool. They and planned economy are two different matters, and they cannot be used to take the place of planned economy. Ours is a socialist country, and a socialist economy is a planned economy in its very essence. Only by persevering in putting all major economic activity on the track of the state plan is it possible to assure the planned proportional development of the national economy. The agricultural economy is a major integral component in the national economy; its development is inseparable from socialist modernization as a whole, and so it positively cannot be divorced from national plan guidance. Our practice of a system of responsibility for production in rural villages has aroused the enthusiasm of the peasants to the maximum extent, and it is, in the final analysis, bringing about, in accordance with state plans, a more rapid, bigger, and more fulsome development of agriculture. Therefore, no matter the form of a system of responsibility practiced, planned economy must likewise be practiced, and a planned economy must likewise be the key link, market regulation supplementary. This is not only advantageous for the country, but is also very advantageous for the peasants. Some comrades suppose that with the practice of systems of responsibility, peasant enthusiasm has increased and products have become abundant, and naturally the peasants will follow the guidance of state plans, so what need is there to emphasize a planned economy as the key link. Experience has shown that the higher the enthusiasm of the peasants for production, the more attention we must devote to strengthening national planning guidance, to inducing the peasants to develop production in accordance with social needs, to prevent and correct blindness and anarchy in production, to prevent and correct a tendency to be concerned only for self without being concerned about the state or the collective, or caring only for present benefits or partial benefits rather than care about long range benefits and all around benefits, and to teach peasants not to "freely" select only the methods that provide them a momentary benefit. Much training has been given in this regard, and we cannot afford to be the slightest bit vague and ambiguous about this.

"Our production patterns here are already very equitable, so what need is there to emphasize taking the planned economy as the key link?" This is something else one hears. That is right. Looked at in terms of the province as a whole, as a result of the clearing away of "leftist" influences, the structure and pattern of agricultural production has gradually become equitable, resulting in a fine situation of all around development of grain production and economic diversification. However, we must realize yet another problem, namely that in a one-sided pursuit of economic income, in some places symptoms have appeared of not wanting to plant a sufficiently large gra grain area and blind expansion of economic crops. Some suburban communes and brigades do not want to grow vegetables in accordance with state plans. Some places do not want to fulfill requisition procurement quotas for agricultural sideline products that have been handed down by the state, etc. Even though these problems are not in the mainstream, if they are not given attention but allowed to develop at will, they will overwhelm state planning and effect the national economy and the people's livelihood. Furthermore, whether or not production patterns are "equitable," cannot be looked at purely in partial terms, but must be judged in terms of the situation as a whole. Some things that look equitable when looked at in partial terms are not only equitable when looked at in terms of the situation as a whole, or may be very inequitable. This requires that we take the whole situation into account and make plans taking all factors into consideration. The overall situations that we are currently emphasizing are basic facts such as the need for 1 billion people to eat, no further national reductions in the grain growing area, and no further increases in grain imports. In striving to make the most of local advantages and potential, we cannot stray from this overall situation, and we must submit to this overall situation.

"Isn't the emphasis on taking a planned economy as the key link a return to the old road of 'arbitrary uniformity'?" Some comrades worry that this is so, and such feelings are understandable because the "gang of four" hoisted the banner of "planned economy" to practice "arbitrary uniformity," the hardships resulting for the broad masses of peasants being truly grave. However, the taking of a planned economy as the key link with market regulation being supplementary that we are emphasizing today is an entirely different matter than what the "gang of four" practiced. First of all, the "national planning" that the "gang of four" espoused was itself a contravention of objective laws and the welfare of the masses. The more planting that was done under this "national plan," the greater the damage to the national economy. But after the past 3 years of bringing order out of chaos, to readjusting, and restructuring, our state plan guidance today is more in accord with natural laws and economic laws, in accord with the welfare of the country, the collective, and the individual, and in accord with the desires of the peasants. Secondly, today production teams and commune members possess self-determination. Through practice, they have created numerous methods that combine the practice of state plan guidance and respect peasant self-determination, things such as the economic contracts that have been promoted, which can dovetail collective and individual commune member production activities with the state plan. Furthermore, when we advocate adherence to planned economy as the key link today, this is not a "great overturning" of the equitable production pattern brought about by readjustments during the past 2 years, but is rather calling for a program based on "positively no relaxation in grain production while actively launching economic diversification" with consolidation of what is suitable and proper further readjustment of what is not suitable. Looked at in terms of the situation as a whole, the proportion of areas sown to grain and to economic crops should be consolidated at present levels. Consequently, to suppose that strengthening of planning guidance means "arbitrary uniformity," is completely erroneous.

Of course, in the process of strengthening planned guidance, individual places or individual cadres may, because of onesidedness in their understanding, manifest a different kind of deviation. Under the pretext of strengthening planning guidance and without regard for complex situations, they may indiscriminately use administrative orders, re-committing the error of blind commanding and "arbitrary uniformity." However, all that is needed is a strengthening of leadership and meticulousness in work, and this kind of situation may be avoided or promptly overcome. Agricultural production in Liaoning Province will certainly be able to gain all-around development while guaranteeing national needs.

BRIEFS

FOREST FIRES--Since this spring, Jinxian County in Jinzhou Municipality, Liaoning Province, has scored great achievements in afforestation, planting over 27,000 mu of trees whose survival rate reaches about 50 percent. Over 13,000 mu of forests have survived. Unfortunately from January to mid-April the county suffered 15 forest fires which burned over 4,000 mu of young growth and barren hills, accounting for 14.8 percent of the forest acreage planted this spring. Most of these fires broke out because the people persist in the feudal superstition of burning paper while visiting their ancestors' graveyard. BRIEFS

DRINKING WATER--Xining, 3 May (XINHUA)--Drinking water problem has been solved in 60 percent of the water shortage areas in Qinghai Province, thanks to efforts made by party committees and governments at various levels in the province during the past few years. By the end of 1981, some 15 million yuan had been allocated by the state to build 610 projects designed to solve the drinking water problem. Some 23,000 kilometers of water pipes have been built, thereby solving the drinking water problem for more than 580,000 people and 3.6 million head of livestock. [OW100347 Beijing XINHUA Domestic Service in Chinese 0029 GMT 3 May 82]

ANIMAL HUSBANDRY--Haidong Prefecture of Qinghai Province has made relatively rapid progress in the past 2 years. Comparing 1981 with 1980, draft animals increased by 23,000 head, sheep and goats increased by 111,000 head and hogs increased by 28,000 head in the prefecture. [SK060854 Xining Qinghai Provincial Service in Mandarin 2330 GMT 5 May 82]

ILLEGAL SALT SALES--The Qinghai Provincial Salt Admiinstrative Bureau recently adopted measures to check illegal salt sales among commune members, disclosing that the annual illegal sales of crude salt amount to over 10,000 tons, causing a loss of over 2 million yuan to the state. Between June 1981 and March 1982, this bureau cracked down on 212 minor and major illegal crude salt selling cases, recovering 278 tons of crude salt. PARAMOUNTCY OF PLANNED AGRICULTURAL ECONOMY STRESSED

Shanghai WEN HUI BAO in Chinese 18 Feb 82 p 1

[Article: "Agriculture Paramount; Planned Economy Paramount. Chen Guodong [7115 0948 2767] Proposes Suburban Production Program Requires Strengthening of Agriculture, Development of Sideline Industries, and Readjustment of Industry For Coordinated Development"]

[Text] At the 16 February Municipal Agricultural Work Conference, Shanghai Municipal CCP Committee First Secretary Chen Guodong analyzed the situation in the economic structure of suburban agriculture, sideline occupations, and industry. He pointed out that the suburbs must adhere to "making the planned economy paramount, and market regulation supplementary," and diligent implementation of a program of "making agriculture paramount in coordinated development of agriculture, sideline occupations, and industry."

Comrade Chen Guodong first affirmed a fine situation in suburban rural villages. He said that in recent years suburban areas had substantially carried out a program of "making the planned economy paramount and market regulation supplementary," and that agricultural production levels were fairly high, making a fairly great contribution to support of industry and urban construction. The masses universally reported that supplies in the market for this year's lunar new year, in particular, were better than in 1981. This was the result of efforts made by the broad masses of cadres and people in the suburbs. However, nowadays a tendency to depart from plan and to grow what one likes has developed in the suburbs, to break up whole lots of collective goods into parts for sale in country fair markets, and to enlarge the proportion of agricultural sideline products sold to the state at negotiated prices. This tendency should arouse the serious attention of our party organization at all levels to do a good job of political and ideological indoctrination of cadres and commune members.

Comrade Chen Guodong also analyzed advantageous factors in Shanghai's development of agricultural production. He said that Shanghai located at the mouth of the Chang Jiang has a temperate climate and fairly good water conservancy conditions, in addition, it has the support of large urban industries, and the support of scientific and technical forces, and it also has conditions for enclosing parts of the sea to make fields. Production avenues are also fairly numerous. Our agriculture should be done somewhat better. But looked at in terms of the situation in suburban agricultural production, the ups and downs have been fairly great. This has been partly the result of natural disasters, but it is also a subjective problem. We should diligently study this problem. The suburbs should go on from consolidation to seek the heights and actively advance, strengthen agriculture, develop sideline occupations, and readjust industry so that suburban agriculture will continue steady forward development.

Comrade Chen Guodong said that in consideration of the long range welfare of suburban peasants, we should accurately handle the relationship between accumulations and consumption, the relationship between the overall and the partial, and the relationship among the state, the collective, and individuals to achieve adjustment between years of plenty and years of scarcity. In addition to the support provided by the state, construction of agriculture currently relies on accumulations from agriculture itself to provide for agriculture and to develop agricultural production.

Comrade Chen Guodong said that we should now strengthen agricultural leadership and not ignore the tendency to leave agriculture. All county CCP committees, commune CCP committees, and brigade CCP branches should devote their main energies to agriculture and place agriculture on their own daily agenda of important things to do. They should particularly enhance ideological leadership in carrying out party programs and policies, and buttress indoctrination in the alliance of agriculture and industry. They should strengthen industrial support of agriculture. They should attach full importance to the application of science and technology and take advantage of the role of science and technology in agricultural production to raise suburban agricultural production to a new level.

This agricultural work conference opened on 8 February and closed on 17 February, lasting for 10 days. Deputy Mayor Chen Zonglie [7115 1350 3525] gave a speech. On the afternoon of the 13th, Municipal CCP leaders Chen Guodong, Hu Lijiao [5170 4539 2403], and Wang Daohan [2076 6670 3211] listened to conference reports and approved the conference. Personnel in charge of counties, communes, farms, and research units as well as persons in charge at relevant municipal units attended the conference.

BRIEFS

ANTIFLOOD WORK CONFERENCE--A provincial antiflood work conference opened in Chengdu on 5 May. Leading comrades from all parts of the province and provincial departments concerned are attending the meeting. Provincial CCP Committee Secretary Yang Wanxuan and Deputy Secretary (Yang Xizhong) made speeches on the opening day. The conference's tasks are to sum up the experiences and lessons of the struggle against flood last year and, on this basis, further enhance understanding of the importance of antiflood work, and map out plans and measures for the work this year. (Liu Chongyi), deputy director of the provincial antiflood command, delivered a report. He said: "According to forecasts by the national meteorological and hydrological departments concerned. There may be further great floods in our province this year. In our antiflood work this year, it is necessary to further strengthen leadership over the work, set up command organs and put them on a sound basis, and map our measures for antiflood and crash-rescue work. Ideologically, organizationally and in measures, we must make full preparations for the province's worst flood since liberation." (Yang Xizhong) stressed: Leading comrades at all levels must have clear understanding of this work this year and get rid of ideas of taking the matter lightly. The departments concerned must do well in medium and short-term weather forecasting. It is necessary to organize flood-fighting forces and materials and be ready to work with local PLA units in fighting floods. TITLE: "Analysis of Structure of Agricultural Production in Zhongshan County"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 1, 8 Jan 82 pp 7-9

ABSTRACT: Zhongshan County is located to the south of the tropic of Cancer in the southern part of Zhujiang delta. The climate is subtropical; the land is flat and crisscrossed by many streams. It has always been known as the home of fish and rice. In 1979, the county has 1,205 thousand mu of cropland, with 68.6 percent in rice paddies, 10.7 percent in sugar cane, 1.9 in mulberry, 1.5 in orchards, 5.2 in other crops, 7.7 in fish ponds, and 4.4 in forage. In the 60's, the yield of dual crop of rice averaged 727 jin/mu, an increase of 34 percent over the previous decade. In the 70's, the average is 914 jin/mu and the increase is only 20 percent, except for one year, 1977, when the yield exceeded a thousand jin/mu. The yield increase potential remains very great if the production of grain is not overemphasized. Modernized agriculture should mean a structure of crops, forestry, animal husbandry, auxiliary industries, fishery, and industries of avery, entomology, and microbes, based upon natural and economic realities of the locality. Possible revisions of the existing structure of farm production to make it more reasonable for the benefit of the locality are discussed, with emphasis on the shortcomings of the triple crop [early and late rice crops, and winter grain] system and possible ways of varying it.

TITLE: "Arrangement of Breeds of Rice on the Basis of Cumulative Temperature and Safe Period Considerations"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCE] in Chinese No 1, 8 Jan 82 pp 11-14

ABSTRACT: This paper analyzes the requirements of a safe growth and development period and cumulative temperature of rice breeds of different maturing times in the region of Shaoqing. Through a clarification of the difference in the condition of cumulative temperature of different areas and the safe seeding and heading time of different breeds, the paper seeks to explain the relationship between high yield and stable yield of paddy rice. There is a detailed analysis of the relationship between the cumulative temperature and stable yield of breeds of different maturity characteristics, which are classified into the 3 types of early ripening, intermediate, and late. The situation is, of course, further complicated by the dual-crop system of early and late rice crops. Discussions are in terms of principles; temperature requirements of specific breeds are mentioned in footnotes to serve as examples only.

TITLE: "On The Intensive Management [Policy] of China's Agriculture"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS OF AGRICULTURAL ECONOMICS] in Chinese No 1, 23 Jan 82 pp 3-8

ABSTRACT: It matters not how China's agriculture is to be modernized, the basic route to development is intensive farming. There is absolutely no doubt about the matter; the only problems to be seriously investigated are ways of intensive management. Intensive farming means the opposite of extensive farming. That is to say, in relative terms, more productive materials and labor are invested in a given area of land, with ever advancing technical measures to work the land in more precise detail. These measures may vary in the 3 types of labor intensive, capital intensive, and technology intensive. Judging from the current conditions of China, proportionally, i.e. compared with developed countries of Europe and America, China has less cropland and less materials to be invested. What China has and must depend on is her abundant labor force. In fixed asset equivalent, each labor force is only worth 250 yuan, to be responsible for 5 mu of cropland and in the same sense each mu has the average worth of only about 50 yuan. Hence, of the 3 types, China's belongs to the labor intensive type of farming. In a very exhaustive analysis, this paper attempts to plot an optimal approach to agricultural modenization through defining intensive farming in terms of maximum benefits permitted by the realities.

TITLE: "The Passive Situation of Concentrated and Excessive Logging of China's Major Forests Must be Changed as Soon as Possible"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS OF AGRICULTURAL ECONOMICS] in Chinese No 1, 23 Jan 82 pp 9-12

ABSTRACT: Since the liberation, the State has invested 6.9 billion yuan and constructed 100 thousand km of roadways to develop remote forests and close to 1 billion m^3 of timber has thus been accumulated. Forestry remains the weakest link in the national economy, however. The coverage is low, only about 12.7 percent of the 70 percent mountainous areas of the territory; the timber consumption has been excessive; and the vegetative coverage rate of these forests is deficient. This paper presents the historical facts of China's forestry industry and its precarious condition today. A 7-point program is proposed to counter these shortcomings, including an immediate and radical change of the logging policy. Forestry data of England, W. Germany, Finland, Sweden, etc. are offered to show the backwardness of that of China.

TITLE: "Preliminary Investigation of Agricultural Development Strategies of the Huanghe-Huaihe-Haihe Region"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS OF AGRICULTURAL ECONOMICS] in Chinese No 1, 23 Jan 82 pp 19-24

ABSTRACT: In the summer and autumn of 1981, the authors participated in the project of the National Committee of Agriculture to carry out a comprehensive agricultural and ecological investigation of the Huanghe-Huaihe-Haihe Region. The key points of investigation are: (1) The low plains of Hebei, Shandong, and Henan, including the Cangzhou Prefecture and Hengshui Prefecture of Hebei, the Huimin Prefecture and Dezhou Prefecture of Shandong; (2) The Huanghe and Huaihe Plain, including Shangqiu Prefecture and Zhoukou Prefecture of Henan and Suxian Prefecture of Anhui. The improved ecological environment of the region is described, before the paper proceeds to discuss the energy transfer and material cycle characteristics of the region. Finally, based upon the observed facts, a strategy and directions of development of that region's agriculture are proposed, with some extensive evaluation of those problems of the region that require immediate attention.

TITLE: "Preliminary Discussions of Cost Accounting of Agricultural Products"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS OF AGRICULTURAL ECONOMICS] in Chinese No 1, 23 Jan 82 pp 37-40

ABSTRACT: In the course of agricultural readjustment to improve the economic benefits of agricultural production and to accelerate agricultural modernization in the province of Henan, the authors believe that the problem of cost computation of agricultural products should not be overlooked. Since the 11th plenum of the 3rd congress of the party, a system of responsibility in varying forms has been established throughout the province. The masses of farmers are thus content and there is unprecedented positive feeling about work. Statistical data of 1980 still indicate a low level of economic benefits, however; they have not been restored to the level of 1957. This paper explains the importance of cost accounting of agricultural products and its function in reducing cost and increasing benefits from the viewpoint of economics. Generally speaking, instead of treating yield increase and thrifty operation as contradictions, cost computation unites the two so that the yield is not only a material transfer of live labor but also its crystallization. The essence is to use minimum labor to achieve maximum benefit. The technique is described and justified.

TITLE: "A Debate That Has Aroused Widespread Attention"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 3, 23 Mar 82 pp 3-7

ABSTRACT: The debate concerning guaranteed production and work has persisted everywhere in the nation for as long as 3 years. Judging from the 3-year practice of Liuan, affirmative answers have been produced with respect to the debates about the time, the direction, the method, the limits, and the prospects. In 1978, the region suffered the greatest drought in 200 years. When the system of twofold responsibility was adopted in 1979, only 16 percent of the production teams participated. The number jumped to 90 in 1980 and 98 percent in 1981. The drought persisted in these 3 years. The 1981 data show that the total grain yield of the prefecture reached 5,200 million jin, an increase of 24 percent over the previous year and 4.6 percent over the highest historical record. The yield of oil products was 3.1 million dan, $1\frac{1}{2}$ times of the record year of 1980. Yield of flaxes, tea, and silkworm all increased more than 10 percent over the highest historical records. The distributed income averaged 123 yuan/member, an increase of 96 percent over 1980. The income from family auxiliary industry averaged 53 yuan/person, an increase of 59 percent over 1980. Adding the 2 items together, the net income per persons was

[continuation of NONGYE JINGJI WENTI No 3, 1982 pp 3-7]

176 yuan, a net increase of 80 yuan over that of 1980. It is estimated that the prefecture will have 1,200 million jin of grains added to its granary, an increase of 200 million jin over 1980. More than 77,000,000 jin of oils have been sold and delivered, 5.6 times the quota of the statistical plan and 2.27 times of the same period of 1980. More than 1.16 million dan of flaxes have been sold and delivered, amounting to 173.5 percent of the planned quota; 98,300 dan of tea leaves, amounting to 110 percent of the quota; and more than 700 dan of silkworms, amounting to 111 percent of the quota. With increases of agricultural production, income, and contribution [to the State], very obvious changes have also occurred in the improvements in clothing, food, lodging, and travel of the commune members.

TITLE: "Preliminary Viewpoints Concerning the System of Individual Household Responsibility for Agricultural Production in Guizhou Province"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 3, 23 Mar 82 pp 8-12

ABSTRACT: The paper explains the househood work contract as a simpler form compared with the household production contract system. With the latter, the way that is practiced in most communes and bridges is that under the unified leadership, planning, and distribution authority of the production team, all the production responsibilities ofthe team are contracted out respectively to each household, practicing a system of fixed production, expenditure, and distribution according to labor points, with awards for exceeding the quota and penalties for shortages. With the former, under the condition of preserving the existence of the production teams, the land is distributed to member-households of the entire team to permit each household to complete the quota responsibility, with the collective keeping a percentage and the household keeping all the surplus products [if any is left.] The author believes that the former system is both natural and reasonable. According to the conditions of the province, the prospects of this system are very good.

TITLE: "Transform the Farming Systems of Zhejiang to Conform With the Principle of Ecological Balance"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 3, 23 Mar 82 pp 24-28

ABSTRACT: Soon after the liberation, in 1955, the grain yield of Zhejiang was brought from the 340 jin/mu level to 544 jin/mu to realize self-sufficiency; in 1966, it reached 874 jin; in 1972, 1,082 jin; in 1979, 1,394 jin. The total grain production of the province was raised from 8,600 million jin of 1949 to 31,200 million jin of 1979, a 2.6 times increase in total yield and 3.1 times in unit yield. Each person's grain ration was increased from 413 jin to 850 jin, more than doubled. There were also large scale increases in the production of other economic crops and animals. From 1949 to 79, the cotton increase was 8.8 times, rape 1.6 times, jute and kenaf 14.5 times, silkworm 4.5 times, tea 8.9 times, cane sugar 7.8 times, citrus 5.9 times, pigs 5.3 times, and marine products 10.4 times to demonstrate the obvious results of of changing the cropping system from intercropping to continuous cropping, from single crop to dual crop, from intermediate rice to late rice, from dual crop to triple crop, etc, yet the yield is not stable, the soil fertility is decreasing, and the economic benefits are not high. Many regard these bad results as the natural consequence of

[continuation of NONGYE JINGJI WENTI No 3, 1982 pp 24-28]

the changes of the cropping system but others believe they are not the necessary results but are created by improper measures in the process of changing the system. If the former belief is correct, the system should just be regressed without consideration of the interests of the State, the collective, and the members. The author believes that the latter is the correct one, however. He states his reasons for this belief and proposes that the current system is in need of correction, based upon the following ideas: (1) Agricultural ecology; (2) Plant nutrition; (3) Agricultural economics. These ideas are explored and some concrete suggestions offered.

TITLE: "Structural Problems of Agricultural Production in Guizhou Province"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 3, 23 Mar 82 pp 29-33

ABSTRACT: Of the province's 177 thousand km^2 of land, 87 percent are mountains, 10 percent hills, and only 3 percent flatlands, interspaced among the mountains and hills. Of the 5380 thousand mu of flatlands, only 930 thousand mu are cropland. Ever since the ancient times, the saying has been "there are no 3 continuous clear days, 3 continuous li of land, or 3 fen of silver in the pockets." With diligence, the province is now a prosperous region. This paper reviews the historical and the current conditions, with emphasis on the serious unreasonable problems in the production structure, which include continuous deforestation to cause the vegetative cover to be reduced to 14 percent about the same as the early years of the liberation, continuous expansion of cropland at the expense of auxiliary industry, animal husbandry, fishery, etc., extensive farming practices to result in planting a lot and harvesting a little, and a devastating erosion problem of losing 4 mm of topsoil a year. These problems and countermeasures are discussed.

TITLE: "How is the Trial Production of Mixed Animal Feed in Rural Areas Promoted by Jinhua City"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 3, 23 Mar 82 pp 38-41

ABSTRACT: In consideration of technological requirements and the spirit of serving current production, soon after the party's Third Plenum, Jinhua City began to experiment on a project of extending the production of mixed feed. Judging from the practice of the project in these 4+ years (1978 through 1981) the mixed feed has proved to be so much better than original single feed, which was actually feeding the pigs etc. whatever was available. Now, pigs are ready one month sooner at 20 percent reduction of cost. Mixed feed is now generally adopted to raise pigs and dairy cattle. In the process of encouraging the production and use of mixed feed, technicians are organized to carry out on site surveys and to proceed with teaching reformed technique of feeding animals. Different formulas of mixed feed are devised according to the available raw materials of each locality and at the same time plants are also organized to process feed. The economic management, i.e. the cost and price structure of feed materials, is changed for the convenience of the masses. In all these, the leaders of the party and the departments keep close touch with one another to bring about the successful results.

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 3, 1982 pp 10-11

ABSTRACT: Techniques of vegetative propagation of ramie include bundling, branching, layering, and planting cuttings. The first is the traditional technique, reported previously in this journal (No 2, 1978) and is omitted in this paper. That is to say this paper introduces only the newly developed techniques, which include: (1) Branching: It was introduced to Hubei in 1980 in more than 10,000 mu of ramie fields. (2) Layering; (3) Cuttings; (4) Cutting into small bundles, a development from the old bundling technique first studied in Japan in 1933-35, by Institute of Flax Crops, Chinese Academy of Agricultural Sciences in 1974-76, before systematic extension in China. The concrete procedure of each of the 4 techniques and its advantages and shortcomings are discussed.

TITLE: "A Survey Report of Sui County Cropping System"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 3, 1982 pp 12-15

ABSTRACT: Sui is the largest county in Hubei and is also one of the important cotton and grain bases. In late Jun to Early Jul 81 the authors went to the 3 representative communes of Yingdian, Yunchuan, and Luoyang of that county to carry out a survey of the cropping system there. The paper reports the fast development of agricultural production in the county since the liberation. The total grain production of 1979 is 2.5 times that of 1949. In the same 30 years, the increase in cotton production is 6.6 fold. The cropping system has been changed in 3 stages: (1) The stage of developing the 2-crop system of wheat and rice; (2) The stage of developing the green manure and dual season rice system; (3) The stage of readjusting the acreage of dual season rice and restoring the 2-crop system of wheat and rice. Current problems discussed in the paper including: (1) Too large an acreage of the 2-crop system of wheat and rice; it is in need of being made smaller; (2) The acreage of dual season rice system is too small; it is in need of some restoration; (3)Attention should be given to the problem of general reduction of ground fertility.

TITLE: "Determination of Bud-forcing Effect of Mixing Seeds With 5406"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 3, 1982 pp 15-16

ABSTRACT: 5406 is a multi-function microbial fertilizer, or antibiotic fertilizer. According to past reports, good effects may be obtained if it is used for bud-forcing of rice seeds and mixing with cottonseeds while planting. Bud-forcing with 5406 needs no artificial heating. The heat produced by 5406 actinomyces during their metabolic process is utilized for bud-forcing. An experiment was carried out with the solid 5406 fermentation spore powder produced by the institute, in a ratio of spore powder:residue cake power:fine soil: rice seeds of 0.25 : 5 : 50 : 100. Water is added to form the mixture into balls by hand; the balls are piled in piles 5-6 cun in height on grass mats or disease-free straw and covered with grass or green manure. The steam bud-forcing technique is used for control. The 5406 technique is found to cause seedlings to develop roots faster and to produce 15.3 percent more seedlings above the control. The second part of the paper reports an experiment on using 5406 to mix with cottonseeds for planting. An insecticide is used to mix with cottonseeds in the same manner to form the control. The 5406 technique is found to result in faster growing cotton seedlings. There are also fewer holes with missing seedlings. Compared with the control, 26.6-43.4 percent more holes have seedlings entering the one-true-leaf stage, when all holes are inspected at the same time and planted under identical conditions.

TITLE: "Experimental Determination of the Disease Spreading Ability of Cotton Verticillium Wilt Carriers and Their Chemical Treatment"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 3, 1982 p 23

ABSTRACT: Verticillium wilt is a stubborn fungus disease of cotton. In 1978, the authors began to conduct a field experiment to determine the disease spreading ability of different carriers and effects of their chemical treatment but they were unable to obtain any obvious result in 3 years. In 1981, they changed their experimental technique and some preliminary results have been obtained. The 3 carriers are disease-carrying soil, stubble, and seeds. Chemical treatments include using sulfur, sulfur mixed with thiophanate, sulfur mixed with MBC, fumigating with chlorinated steam, mixing with ammonium carbonate, etc. Results indicate that all 3 carriers can cause an obviously high rate of diseased cotton plants, with the of diseased stubble the highest and that of diseased seeds the lowest. Treatment of diseased seeds with thiophanate is effective for controlling the disease, but the germination rate is also obviously reduced.

TITLE: "The 800 Million Farmers Need Planning"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 2, 5 Feb 82 p 5

ABSTRACT: This paper first reviews the progresses that have been made since the Third Plenum of the Party Congress, resulting mainly from the following 3 policies: (1) Redressing leftest errors and loosening up policies; (2) Raising the prices of agricultural auxiliary products; (3) A given quantity of grains are to be imported every year. It is definitely correct that farmers should be made rich;the question is how. Do whatever one is willing to do and depend upon the State to provide benefits just will not do. Under the direction of the State's plan, the attention of the farmers should be drawn to production development, to tap their internal potential, to improve operation and management, to practice scientific farming, and to raise economic benefits so that rural villages may become rich gradually in a healthy way. There is not the slightest doubt that agricultural economic activities must be brought into the State's planning track. Concretely speaking, such products as grains, cotton, and oil should have definite quotas to practice unified purchase. There should be a base quantity of purchase for farm auxiliary products. In this manner, the State and the farmers may know what to expect. The contract system should be gradually extended and strictly executed, to bring together the plans of the State and the production arrangements of farmers.

TITLE: "Realistically Strengthening the Leadership of the Basic Level Organizations of Rural Villages"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 2, 5 Feb 82 p 9

ABSTRACT: Due to the establishment of various forms of system of responsibility in agricultural production, the vast number of farmers in China are greatly stimulated to pursue production, but in some places, as the leadership is loosened,the leadership groups of production teams begin to relax the discipline and even become paralysed. As a result many jobs have no one to be responsible for and various goals and policies of the party cannot be completed. The objective of the production responsibility system is to solidify the collective economy and is not to negate it. Hence, implementation of the production responsibility system does not mean that cadres of brigades and teams are to let down their burdens. The responsibilities and jobs of leaders of rural village organizations under the present condition are discussed, emphasizing the importance of strengthening these organizations.

TITLE: "Effectively Improve Pig Production"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 2, 5 Feb 82 p 20

ABSTRACT: In China, pork amounts to 90 percent of the meat consumption in cities and rural areas alike. Pork is also one of the important auxiliary farm products for export. In the past several years, a series of mistaken policies of forbidding or limiting the practice of raising pigs have been abolished by the party and some concrete measures have been formulated to encourage the commune members to raise pigs. Since then, the total production of pork has been rising quickly until last year. Toward the end of last year, there was a reduction of the number of pigs in the sties or in the marketplace and the number of sows and hogs is also decreasing. The lax of leadership, the improper handling of the three-way relationship of the State, the collective, and the individual, less than strict management of the market to cause illegal slaughter of pigs, and many problems of purchase, processing, transport, storage, etc. are all factors contributing to the decline of the pig-producing industry. Some production teams distribute the feed-producing land to the members who plant whatever that will bring a greater profit.A series of realistic measures are proposed in the paper to correct these errors and to revive the pig-producing industry.

ORG: Green Manure Group, Institute of Soil and Fertilizer, Chinese Academy of Agricultural Sciences

TITLE: "An Investigation of the Development of Green Manure Production in North China"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 2, 5 Feb 82 pp 45-46

ABSTRACT: The 15 provinces, cities and regions of North China have 390 million mu of cropland. Green manure was cultivated in 2.7212 million mu of these in 1979, amounting to a 52.4 percent increase over the acreage in 1975. At present, the green manure acreage remains only 3.27 percent of the cropland. The increase is, therefore, far from sufficiently fast. The main reason is the fact that green manure crops have not received the proper attention of the leaders, who have a fixed notion of depending upon chemical fertilizer to produce grains now. At present, soil fertility of the North is declining, in a great scale in many places and there is insufficient source of organic fertilizer while the condition for developing green manure is good. The many advantages of developing green manure crops and ways of cultivating them are discussed.

ORG: Policy Research Office, Ministry of Forestry

TITLE: "Several Problems of Policy Concerning Forestry"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 2, 5 Feb 82 p 47

ABSTRACT: In the form of answers to 6 questions, this paper discusses the ownership of forests and ways of settling ownership disputes if any. (1) If the mountain and the forest belong to 2 different units, how are the [ownership] right certificate to be issued? The answer is that mountain and forest rights should be unified, but if not, separate certificates should be issued. (2) How is the problem of several units owning intersecting pieces of a mountain and/or a forest to be resolved? It should be resolved through voluntary exchange of these pieces on the basis of mutual benefit and equal value. If no exchange is possible, the current condition should be preserved. (3) Should forest land and sparsely forested land be given to the masses for keeps? No, not in large pieces, but a few trees may be sold to commune members at a reasonable price or a contract may be signed for the member to take care of the trees for a portion of the profit. (4) Who owns the mountains and forests that have never been brought into a commune? They are owned by the collective body and the member who has been taking care of them should be rewarded by the collective or be paid on a contract share profit

[continuation of NONGCUN GONGZUO TONGXUN No 2, 1982 p 47]

basis. (5) What is to be done for the mountains and forests belonging to the workers of towns and cities and the inhabitants of rural villages? If after collectivization, the collective acknowledged the ownership of these mountains and forests to be these individuals they should remain to be theirs. If these mountains and forests had been included in the collective they cannot be returned to the individuals [previous owners.] (6) How are disputes concerning ownership of mountains and forests to be resolved? Disputes should be resolved on the basis of the principle of strengthening solidarity and the principle of forest protection and development. Whether the dispute is between the State and the collective or between a collective and its members, the leader above the rank of the party in the dispute should supervise a negotiation between the parties. If the negotiation should fail to bring about an agreement, a judgment from the people's court should be requested. The court may dispense the necessary penalty to the party who willfully carries on the dispute and refuse to listen to either the leader or the court.

TITLE: "A New Sugar Crop: Sweet-leaf Chrysanthemum"

SOURCE: Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 1, 24 Jan 82 pp 22-23

ABSTRACT: The Jiangsu State-farm and Land Reclamation System has been extending sweet-leaf chrysanthemum [Stevia rebaudiana] over large acreages in recent years. It is a perennial of the genus Chrysanthemum, a native of the border mountains of Paraguay and Brazil, in S. America. Its leaves contain a glucoside and are 150 to 300 times sweeter than sugar cane. After the recent discovery of the harmful effects of saccharin, some countries have banned or limited its use, while the production of sugar cane and beets cannot yet satisfy the needs of the world. At present, this chrysanthemum is being extensively cropped in Japan, the USA, Paraguay, S. Korea, Romania, Thailand, etc. It was introduced to China from Japan in 1977 by the Nanjing Institute of Botany. Since then, it has been extended to 27 provinces, cities, and autonomous regions, including the Northeast and the Northwest. In 1979-80, a dried-leaf product was supplied by Jiangsu and Fujian for foreign trade. The 1980 experiment of the bureau demonstrates that its cost per mu is 75 percent of that of cotton but its yield is worth 150 percent. The paper includes a description of its culture techniques but only briefly the process of refining it into a sweetener.

TITLE: ["Growth of Cottonseed and Its Metabolism"]

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 5 Apr 82 pp 6-8

ABSTRACT: The weight of a cotton boll includes the weight of fibers and that of the seeds. The latter is an important factor of the yield. This paper reports a study on the process of growth of cottonseed and their metabolic change regarding the sugar, nitrogen, fat, and fatty acid contents to provide a scientific basis for improving the cultivation technique and for selective breeding. The growth of cottonseed is found to be divided into 2 stages: that of the volume, which is generally fixed at 28 days after blooming, and that of filling, i.e. the weight. The key weight increasing period begins at about 4 weeks after blooming and ends at boll-opening. As it has been pointed out by previous studies, the branch and leaves in the vicinity of the boll contain a high level of sugar and nitrogen at the time of boll-opening; therefore, they should not be removed during trimming. The fat content of the seeds is generally above 34 percent and more than 54 percent of this is linoleic acid; therefore, cottonseed oil is a highly nutritious edible oil, if the phenol content is removed first. The residue cake is a good protein feed.

TITLE: "Research on Interspecific Hybridization of Upland Cotton and Anomal Cotton"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 5 Apr 82 pp 9-10, 30

ABSTRACT: The African anomal cotton (G. anomalum) belongs to the B_1 chromosome group (2n = 26). When it grows in the wild, it has very high resistance to bollworm and red spiders. Its fiber is extremely fine and strong. In the USA, its hybridization with upland cotton has produced male sterile material. Similar experiments in the USSR have produced hybrids of 65 chromosomes. In 1980-81, the authors crossed it with upland cotton (G. hirsutum) and doubled the chromosomes of the F_1 to obtain 18 interspecific hybrids. Although the F_1 is highly sterile, when colchicine solution is used to treat growth points of various locations of F_1 plants, fertility is restored to produce first generation seeds of the hybrid.

TITLE: "Research on the Rooting Ability of Rice Seedlings: Second Report: Effects of Temperature on the Rooting Ability of Seedlings"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 5 Apr 82 pp 11-13

ABSTRACT: Effects of ecological types of rice breeds and seeding quantity on the rooting ability and the material conditions in the rooting process were reported in the first report of this study. In this, the second report, effects of temperature variations on the rooting ability of seedlings in Shanghai suburbs are studied. Results demonstrate that temperature sensitivity with respect to root development varies with the breed. In case of Guangluai, the most commonly used local breed of early rice, the minimum temperature requirement for rooting is 14.4-14.9°C. For Yuanfengzao, the second favorite, which is used in considerablely smaller acreages in that locality, the minimum temperature requirement is 15.6-18.0°C. Judging from the local statistical data on temperature variations, it is safe to transplant Guangluai after the 1st of May, but Yuanfengzao should not be transplated until the 11 May. In a cooler year, the latter may have to be delayed 5 more days.

TITLE: "A Study on the Stability of Physiological Strain of Rice Blast Pathogens and the Classification of Breed Resistance"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 5 Apr 82 pp 14-16, 20

ABSTRACT: A blast resistant breed of rice may gradually lose its resistance in the cultivation process. In the past decade, scientists here and abroad performed a great deal of work to investigate the stability of blast resistance and they have proved that the major factor determining blast resistance of a rice breed is the distribution of physiological strains of the pathogens. This paper reports an inoculation test of 7 local rice breeds with 31 representative and relatively stable strains. About 50 percent of these physiological strains were found to be stable continuously for 2 years and about 70 percent are basically stable in one year. It appears that the development tendency of blast may be predicted by the increase or decrease of the locally dominant toxic strain. This is, however, only one factor for the occurrence of a severe incidence. An unfavorable weather condition is the leading factor.

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 5 Apr 82 pp 28-30

ABSTRACT: An experiment was carried out using Shanghai White Swine as the mother, and 5 other breeds as the father to compare the rate of lean meat of the hybrids. The piglets, 6 of each hybrid group are fed the same way for 4 months before they are slaughtered for comparison. The Shanghai White-swine x Duroc hybrids are found to have the highest rate of lean meat. The rate of lean meat of hybrids of all the other groups is higher than that of Shanghai White-swine x Shanghai White-swine, howver. Under the current condition of short supply of Duroc hogs, the other breeds should be used to serve the purpose of improving the lean meat rate of pigs. Effectiveness of crossing the hybrid with another lean breed is to be studied in the future.

TITLE: "Preliminary Summarization of Early Rice High Yield Experiences"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 5 Apr 82 pp 43-45

ABSTRACT: In 1981, Shanghai suburbs planted 1.52 million mu of early rice, with an average yield of 804 jin/mu, amounting to an increase of 17.9 percent over the yield of 1980. Judging from the yield structure, the increase is accomplished through an increase of the number of spikes and grains. The major experience is improving and perfecting the joint production responsibility system, which causes the commune members to feel positive about carrying out various cultivation measures. These measures include timely and sparse seeding to cultivate strong seedlings with tillers [at the transplanting time;] dry plowing and deep application of basic fertilizer; early transplanting of all needed seedlings; and using promoting and controlling measures to guarantee early development, stable growth, and ripening on live and green stalks. Detailed data concerning these measures and the excellent results are reported.

TITLE: "Bringing Out the Spirit of Yanan to Construct a Better North Shaanxi"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 3, 1982 pp 5-7

ABSTRACT: Although in 1968-78 the State sent to Northern Shaanxi more than 700 million jin of grain, as a result of devastation by the "cultural revolution" and leftest ideas, the people of Northern Shaanxi still did not have enough to eat, wear, or spend. The average food ration was 200-300 jin/person and 30 percent of the farmers suffered hunger. In 1979, after the historical turnabout achieved by the 3rd plenum of the party congress, the region experienced continuous bountiful harvests, in spite of the continuous natural disasters of drought, flood, pest, hailstorm, etc. and yield increases have been sustained year after year. Measures adopted by the party to produce such overwhelming changes in the short period of 3 years (1979-81) are reported. Targets set for every year until 1985 and beyond include the realization of a large animal, 9 mu of woodland and grassland, 800 jin of grain, and 5 sheep for every person. The region has rich resources and a great potential. Reasonable development and utilization are being awaited.

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 3, 1982 pp 14-15

ABSTRACT: Following the system of responsibility in agricultural production, the system of technology contracting is another new event. Most recently, the Chinese Scientific and Technical Association called A Conference for Exchanging Experiences of the System of Agricultural Technology Contracting (Including Diversified Production). This paper reproduces 3 reports to that conference, delivered by Zhangmu Commune Science Popularization Association of Yulin County, Guangxi Province, the Tinggong Commune Science Association of Xiayi County, Henan Province, and the Shiyan Commune Science Association of Ningan County, Heilongjiang Province, to illustrate the many successful stories heard at the conference.

TITLE: "Water and Soil Conservancy Cropping Technique Should be Extended in the Middle Reaches of Huanghe"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 3, 1982 p 16

ABSTRACT: The middle reaches of Huanghe form the most seriously erroded region of China. The problem can be resolved only through comprehensive soil, water, and afforestation measures of water and soil conservancy in the entire region. In the 50's and 60's, various water and soil conservancy cropping techniques were extended in many places of the loessial plateau, such as Gansu and Northern Shaanxi to produce very good results. There are many such cropping techniques. The most common ones include horizontal contouring of the slopes, constructing ridges in fields, digging parallel ditches to reduce runoff, etc. At present, these cropping techniques have been established for 40 million mu of cropland of the middle reaches of Huanghe, but there are 120 million mu of fields on mountainous slopes yet to be treated. The paper does not include descriptions of the condition of erosion. It only discusses the advantages and the possibilities of stopping erosion in that region.

TITLE: "Condition of Supply, Demand, and Development of Several Major Farm and Animal Products"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 3, 1982 p 29

ABSTRACT: This paper provides, briefly, the supply, demand, and development data of grains, soybean, rape seeds, tobacco, ramie , and pork. The data cover roughly the years of 1979, 1980, and 1981, but not in an organized manner. Regarding grains, the annual consumption is about 650 jin/persons at present. If this level is to be maintained, with the natural yearly increase of population, an increase of production of 10,000 million jin a year is necessary. Regarding soybean, with the 40 percent reduction of acreage, the yield is about 20 percent less (1981). The State has spent 120 million US dollars to import 800 million jin a year but the demand is still not met. Regarding rape, the acreage has been increased to 19,000 thousand mu in the past 3 years, but the oil is too expensive and of too low a quality for export. With respect to tobacco, the acreage is 3,080 thousand mu larger in 1981 over that of 1980, and expanding in spite of the decision of Heilongjiang Provincial Committee to reduce it. With regard to ramie, the State is unable to develop spinning and weaving facilities; therefore, there is a backlog. The pig population of 1981 is 15,400 thousand less than that of 1980; some provinces are beginning to adopt policies to improve the situation.

TITLE: "Hold Fast Some Key Measures to Develop Swine Production"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 3, 1982 pp 41-

ABSTRACT: For the purpose of promoting the development of the industry of raising pigs and changing the current situation of production decrease, the provinces, cities, and autonomous regions, heeding the notification of the State Council, are adopting effective measures to resolve some key problems. Measures being adopted include the following: (1) A policy of rewarding pig production: Zhejiang Province resolved that production teams may subcontract pig-raising jobs with feed to families who may sell pigs to the State directly; if no pigs are produced, the feed must be delivered back to the State; (2) Zhejiang Province requires the various areas under her jurisdiction to increase the current 800 thousand hogs and sows to one million. Shaanxi Province requires that the number of sows must amount to 8-10 percent of all herds of swine while the number of hogs must be 4 percent of the number of sows. These measures are to guarantee the supply of piglets. (3) Three-year contracts are to be signed by the departments of food products to purchase a given number of pigs from designated production teams who may contract the jobs to families. After fulfilling the contract responsibility, as it is clearly stated on the contracts, the surplus pigs [if any] may be slaughtered and consumed by the owners.

ORG: Rural Purchase and Sale Bureau, Ministry of Grains

TITLE: "State's Purchase Quota May not be Fulfilled by Grains Bought From the Marketplace"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 3, 1982 p 45

ABSTRACT: It has been reported that as some production teams are exercising their right to self-determination, they begin to consider the size of economic benefit of themselves and go to the marketplace to buy grains to fulfill their grain sale quota distributed by the State. The paper attempts to explain the bureau's disapproval of such a practice. The reasons are stated as follows: (1) The economic activities of production teams must follow the directive of the State's plan; (2) The policy of not overlooking grain production while developing multiple operations must be seriously implemented; (3) Production teams must guarantee the fulfillment of the State quota of grain purchase; (4) The marketplace [the prices] and the grain production must be kept stable. If production teams and commune members were allowed to buy grains from the market to fulfill their quotas, the price of grains will necessarily rise and the prices of all other related products will fluctuate as well. It will be extremely difficult to arrange the livelihood of commune members. This is unfavorable for the State, the collectives, and the individuals.

TITLE: "On the Reasonable Technique of Irrigation"

SOURCE: Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 3, 1982 p 2

ABSTRACT: Scientific farming includes reasonable irrigation. If water is not applied scientifically in agricultural production, there will often be unfavorable results. For example, in the early 60's, in some provinces of China, such as Henan and Shandong, in some irrigation regions where the water of the Huanghe was drawn, a gigantic quantity of water was applied to result in soil salinization and a large scale yield reduction of crops. This paper explains the technique of reasonable irrigation in terms of the following: (1) There must be a water use plan to apply water on the basis of the moisture requirements of the crops, for example 300-400 m^3/mu for wheat, 250-300 m^3/mu for corn, and 300-450 m^3 for cotton. It is definitely not true that the more water is applied the more is the yield. (2) The time for water application should be determined by the variation of the weather. For example, in 1980, there was very little rain in Jul and Aug in Xinxiang Prefecture of Henan. It appeared that the wheat crop would suffer, and as the technique of weather forecast was not mastered some areas applied water. On the 8th and 9th of Oct, 50 mm of rain fell continuously to result in utter disaster in those areas.

TITLE: "The 'Sparse, Few, and Steady' Culture Technique for Early Rice"

SOURCE: Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 3, 1982 p 4

ABSTRACT: The technique of "sparse, few, and steady" means sparse seeding to obtain strong seedlings, transplanting few seedlings in a unit area, and steady applications of fertilizer and water to protect the leaves and promote the roots. With this technique, generally speaking, one mu of seedbed will produce enough seedlings for 5-8 mu of paddies, amounting to a reduction of 40-60 percent, compared with the seedbed use of the common culture technique. About 10-12 jin of seeds are saved for the yield of every 1,000 jin of rice grain, as well as a saving of 0.46-2.71 work-day and 0.46-7.68 yuan of the cost. For each mu, the yield increase with this technique may reach 40-122 jin. This culture technique and its advantages are described.

TITLE: "Growth Development Principle of Wheat and Its Field Management"

SOURCE: Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 3, 1982 pp 5-6

ABSTRACT: The meteorological conditions of China's wheat production regions of the south and the north vary a great deal. Even within a single region, the condition of the wheat crop will vary with the different breeds used, the different external conditions of the weather, the soil, etc. and the different cultivation measures. The field management for wheat should,therefore, be determined by the conditions of an individual locality. The common goal is to obtain strong seedlings, however. Four standards are proposed to define strong wheat seedlings: broad and green leaves, normal shape of plants, timely growth, and tillering in stages. Each region should set its own concrete standards for strong seedlings according to the concrete conditions of that locality, for the purpose of applying proper and timely production measures for promoting or controlling the growth of the plants to meet the requirements of these standards. The various expressions of strong seedlings, regardless of breeds and other differences of conditions, are described separately in terms of stages of growth and development, including the young seedling stage, the stage of organ formation, etc. Indications of excessive growth and deficient growth are described for every stage, with discussions of proper countermeasures.

TITLE: "Another Haploid Breeding Method--The Corm Barley Technique"

SOURCE: Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 3, 1982 p 31

ABSTRACT: Haploid breeding has become very common in experiments in recent years. It is a technique of obtaining haploid plants from anther culture, such as the technique introduced in a paper in No 1, 1978 issue of this journal. The present paper introduces a different technique which has become successful in some countries [not specified in the paper] of the world. This is the technique of using common barley as the mother and corm barley as the father. After hybridization, all chromosomes of corm barley are eliminated so that the resultant embryo contains only a set of chromosomes belonging to the common barley. The induction rate of this technique is much more stable than the anther technique. According to experimental data, an ideal hybridization grouping may thus be obtained. The concrete procedure of this new technique is described. This paper does not mention any experiment or experimental data carried out in China, however.

TITLE: "Eradication Program for Enzootic Pneumonia of Pigs"

SOURCE: Nanjing XUMU YU SHOUYI [ANIMAL HUSBANDRY AND VETERINARY MEDICINE] in Chinese No 6, 20 Dec 81 pp 29-32

ABSTRACT: According to a statistical report of Shanghai, of the 3 million pigs marketed, due to swine pneumonia, piglets' weight gain is reduced 14-23 percent daily over a 65-day period; at an incidence of 20 percent, 600 thousand piglets in a year have to be fed a month longer due to this disease, an equivalent of a meat loss of 100 thousand pigs. In serious enzootic incidents, a large number may also die. Based upon the theory that the infection is caused by a pneumonia mycoplasmatales existing in the swine respiratory system only and the fact that once they are exhaled, they lose their pathogenicity in 48 hours at 28°C, an eradication program is devised by the authors (1978-79) to identify diseased piglets quickly by x-ray, to isolate the diseased ones from the healthy ones, an accelerated treatment of

[continuation of XUMU YU SHOUYI No 6, 1981 pp 29-32]

the diseased with sodium humic acid, Chinese traditional medicine, antibiotics, etc. injecting the healthy ones with terramycin-almond oil for prevention, and improving feeding and management. Piglets brought from outside areas are screened with x-ray before allowing them to join the healthy ones, etc. By the time this paper was written (Nov 81) no new cases of this disease had been discovered among the healthy ones.

I. GENERAL INFORMATION

NATIONWIDE BIRD PROTECTION PROGRAM URGED

'Bird Appreciation Week'

Beijing GUANGMING RIBAO in Chinese 6 Feb 82 p 1

[Article: "National Bird Appreciation Week Activities Will Begin This Spring, State Council Approves Report by the Ministry of Forestry and Departments Asking To Strengthen Protection of Birds"]

[Text] The nationwide bird appreciation week activities will begin in the spring of this year. This is one of the important measures to protect birds included in the report by eight departments including the Forestry Ministry and approved by the State Council for nationwide implementation.

The Ministry of Forestry, the Foreign Ministry, the Ministry of Foreign Trade, the Ministry of Finance, the Leading Group for Environmental Protection of the State Council, the State Urban Construction Bureau, the Chinese Academy of Sciences, and the Central Committee of the Chinese Communist Youth League have proposed in their joint report submitted to the State Council and entitled "Enquiry Concerning the Implementation of the Mutual Agreement on the Protection of Chinese and Japanese Migratory Birds in Strengthening the Protection of Birds," that the following work conscientiously be carried out:

1. Propaganda and education should be launched in a big way. The week from the end of April to the beginning of May should be designated as "Bird Appreciation Week" (actual time to be set by the provinces, cities, autonomous regions). During Bird Appreciation Week, reporting conferences or discussion meetings can be organized. Experts can be invited to lecture. Youths can be organized to go to the fields, nature preserves, regions where hunting is prohibited, and parks to observe birds, and they can be encouraged to hang up man-made bird cages to protect and lure beneficial birds and to conduct such activities to establish the concept that "everyone has the responsibility of protecting birds" and to gradually develop a habit of appreciating and protecting birds.

2. Protection and management should be strengthened and uncontrolled trapping and hunting of birds must be prohibited. Rare birds to be protected under state laws must be strictly protected. No unit or individual

can trap or hunt, sell or buy and transport protected birds without approval by the administrative forestry departments. Hunting should be prohibited in cities and towns, industrial and mining areas, nature preserves, nonhunting zones, tourist regions, scenic areas and parks. Such hunting devices and methods as the gathering of eggs, destruction of nests and the use of poisons, blasting shells (firecrackers), and air rifles that destroy the resources of birds should be prohibited.

3. More areas should be zoned as nature preserves for migratory birds. It is suggested that the main propagation grounds, the wintering grounds, the main resting grounds along routes of migratory birds, especially islands, lakes, swamps, beaches that have important value in protecting migratory birds within the nature preserves of the nation and the provinces, cities and autonomous regions should be zoned as natural sanctuaries. Those regions that should be protected but for some reason cannot be zoned as a nature preserver can be zoned as nonhunting regions.

4. Tagging work should be launched. Tagging has important meaning in the protection and the rational utilization of migratory bird resources, in scientific research, national defense, plant protection and prevention and control of diseases. Since 1899, the world has tagged over 30 million birds. Nations in east Asia tagged over 1,200 species of migratory birds from 1963 to 1970. Tagging is an indispensable part of implementing the Sino-Japanese bird protection agreement. It will be studied and handled by the Ministry of Forestry together with the Chinese Academy of Sciences.

5. Procurement and export control of bird products should be strengthened. Economic birds and their products are important export materials. Production, procurement and exporting should be organized according to plan and under the prerequisite of not destroying resources. All birds to be protected under state regulation and not approved for trapping by the forestry departments cannot be procured by the departments of supply and marketing, foreign trade, urban construction and flower and bird shops (companies), specimen companies (factories) and zoos; and foreign trade departments must not export them.

Commentator on Bird Protection

Beijing GUANGMING RIBAO in Chinese 5 Feb 82 p 1

[Article by commentator: "Protection of Birds Must Not Be Delayed"]

[Text] Birds are a part of nature and they are a precious resource. Protecting birds has an important significance in maintaining the natural ecological balance. Therefore, protecting and rationally utilizing the resources of birds have become international symbols used to measure the natural environment, the scientific culture and civilization of society, a nation and a region.

In today's efforts to advocate the building of spiritual civilization of socialism in a big way, the approval by the State Council of the enquiry concerning strengthening the protection of birds submitted by the eight departments including the Ministry of Forestry has great significance.

Our nation has 1,175 species of birds, a nation with the most number of species of birds. Our nation can be considered to be "especially endowed." Our nation has 56 species of wild chickens, constituting 1/5 the total number of wild chickens in the world. The whole world has 15 species of cranes. Our nation has nine of them, and among these, the Danding crane and the black neck crane are mainly found in our nation. Yet, our work in the protection and the utilization of the resources of birds falls far behind many nations. The result of a long period of uncontrolled trapping and hunting has forced some rare birds and hawks and vultures to become nearly extinct. This situation should be changed within a short period with an all-out effort.

To protect birds, we must first appreciate birds. Every person in the whole of China should appreciate birds and should cultivate the virtue of appreciating birds. The State Council has decided to launch "Bird Appreciation Week" activities throughout the nation. This is a very important measure. Each department must carry this out. Scientific workers have the unshirkable duty to propagate knowledge about birds. Middle and elementary schools, Chinese Communist Youth League and young vanguard teams must shoulder the heavy responsibility in this regard. They should teach knowledge about birds to the younger generation, and organize and lead them in launching activities to protect beneficial birds. The activity of "Bird Appreciation Week" should be carried out year after year so that a new virtue of appreciating birds and protecting birds will surely be established among the people of the whole nation.

There should be an appropriate increase in the number of nature sanctuaries for birds. Japan has 1,000 bird sanctuaries. Up to the present, our nation has only zoned 10 such regions. It goes without saying that such a number is far too small for such a nation like ours which is so large.

Artificial cultivation of economic birds needs to be strengthened. Foreign nations have created pheasant farms and have raised pheasants on farmland to eliminate the seeds of weeds and harmful insects. All of these things are worth learning. The great lag in the work of artificially raising pheasants in our nation must be urgently changed. Luring beneficial birds also must be highly emphasized and this work should catch up quickly. According to information on Shandong Province, luring grey magpies to the forests can effectively prevent the occurrence of insect pests. Uncontrolled trapping and hunting must be quickly stopped. According to complaints, some factories in at least two industrial sectors are producing air rifles and the number of such guns produced within a year is in the millions. This situation has worried some zoological workers. With such continuous production of hunting weapons, how can uncontrolled trapping and hunting be stopped? The supply and marketing units, foreign trade, flower and bird companies, and specimen factories should all abide by state regulations and conduct business, procure and export birds within the allowable limits. Units and individuals who violate such state regulations and destroy the bird resources must be investigated regarding their responsibility. Units and individuals who have realized outstanding achievements in the protection of birds must be praised and rewarded.

Eight Protection Zones

Harbin HEILONGJIANG RIBAO in Chinese 13 Feb 82 p 4

[Article: "Our Nation Has Zoned Eight Nature Preserves for Birds, They Include the Zalong Nature Preserves in Heilongjiang"]

[Text] According to the latest information provided by the Ministry of Forestry, our nation has zoned eight nature preserves mainly for the protection of birds.

These eight preserves are: Niaodao Nature Preserve in Qinghaihu in Qinghai, Tianehu Nature Preserve in Bayanbulak in Xinjiang; Luyashan Preserve in Shanxi; Pangguangou Nature Preserve in Shanxi; Laotieshan Shedao Nature Preserve in Liaoning; Zalong Nature Preserve in Heilongjiang; Tongyu Nature Preserve in Jilin; Zhenlai Nature Preserve in Jilin. The total area of the 8 preserves cover over 360,000 hectares.

Besides the nature preserves mainly to protect birds, many regions have also zoned areas where hunting is prohibited also to protect birds. Throughout the nation, there are 85 other general nature preserves, most of which also serve to protect birds.

INCREASE IN RURAL, URBAN PURCHASES OF CONSUMER GOODS NOTED

Chengdu SICHUAN RIBAO in Chinese 30 Jan 82 p 1

[Article: "All-Around Increase in Amounts of Food, Clothing, and Goods For Daily Use in City and Country Markets Throughout the Country During 1981"]

[Text] State Statistical Bureau recently provided data shows that in 1981 goods sold in city and country retail markets in China--food, clothing, and items for daily use alike--continued increases in quantities sold.

According to the statistics, in 1981 total retail sales of social commodities was 235 billion yuan, a 21 billion yuan increase over 1980 for a 9.8 percent growth (a growth of 7.7 percent following deduction of retail commodity price rises). Comparison of total retail sales of social commodities last year with 1978 shows a 79.14 billion yuan for 50.8 percent increase. This resulted from increased earnings by urban and country people following implementation of various programs and policies in the wake of the 3rd Plenary Session of the 11th Party Central Committee.

Analysis shows emergence of several new changes in city and country markets during 1981. The extent of rural commodity retail sales increase was larger than for cities. In 1981 city and town commodity retail sales amounted to 102.6 billion yuan, an eight percent increase over 1980; rural commodity retail sales amounted to 132.4 yuan, an 11.3 percent increase over 1981.

Sales of commodities for daily use were greater than sales of food or clothing. In 1981, market sales of 15 major items for daily use including matches, soap,sewing machines, wristwatches, bicycles, and pencils increased 10.5 percent over 1981, sewing machine sales increasing 28 percent, bicycle sales increasing 17.9 percent, and television set sales increasing 44.4 percent. Sales of 10 major food items including grain, edible oil, meat, eggs, and sugar showed increases of only 4.5 percent, while sales of 10 major clothing items including cotton cloth, chemical fiber cloth, and woolens increased by only six percent. This situation shows that the purchasing power of the people has already begun to shift toward high quality, durable consumer goods.

The amount of commodity sales through all circulation channels showed all-around increase, and quantities of goods retailed through supplementary channels showed greatest extent of increase. In 1981, businesses owned by all the people (including the beverage industry) had retail sales 3.5 percent greater than in 1980. Retail sales by collectively owned businesses increased 34.2 percent. Retail sales by the 1.83 million individual households authorized by industrial and commercial administrative departments increased 2.2 fold. Commodity sales by industrial units themselves also increased by 31.5 percent over 1980. Volume of business transacted in urban and rural country fair trade for the year amounted to 29 billion yuan, a 23.2 percent increase over 1980.

The State Statistical Bureau acknowledged the existence of problems in markets at the present time, one of which was that increased sources of supply of retail goods has still been unable to catch up with increased purchasing power demand for social commodities. Vigorous development of consumer goods production must continue, with prompt organization of procurement and expansion of sources of supply. Secondly there has been a tendency toward increase in unmarketable goods in commercial storage in the country. Forces must be organized for conscientious inventorying of overstocked goods, and their sale urgently promoted. Third is the fairly serious incidence of illegal conduct in speculation and profiteering in markets. Effective measures must be taken to put a stop to it.

ATTENTION TO LAMB, KID MEAT PRODUCTION URGED

Lanzhou GANSU RIBAO in Chinese 21 Feb 82 p 1

[Article by Wei Huaifang [7614 2037 2455] and Ge Wenhua [5514 2429 0553]: "A New Way To Develop Lamb and Kid Meat Production"]

[Text] In livestock production and in business and foreign trade, the meat from lambs or goats slaughtered before they are 1-year old in the year of their birth is termed lamb or kid meat. Lamb and kid contain much lean meat, little fat, little of the strong smell of mutton or goat, have abundant nutrients, are delicious and juicy, and are readily digested and absorbed. Formerly in the raising of lambs and kids, emphasis has been concentrated on production of mutton from sheep, and the kid meat production potential provided by goats which make up 38 percent of the combined sheep and goat population, particularly from the fine hybrid variety milk goats, remained to be tapped.

Experiments carried out by the animal husbandry department of Gansu Agricultural University at the Yangxiaba Multiple Test Site in Wuwei Prefecture on "Results in Shaneng Milk Goat Hybrids in Improving Local Goats" showed that not only was the quantity of milk from hybrid goats greatly increased, but also that, happily, hybrid goat meat production also remarkable increased. At age 1-month, first generation Shashi hybrid bucks were castrated. At age 7 or 8 months, their live weight averaged 33.8 kilograms, and their dressed weight averaged 16.8 kilograms. Fats and oils weighed 2.7 kilograms, for a dressing percentage of 49.8 percent. Native varieties castrated at the same age and under the same conditions averaged live weights of only 22. 4 kilograms, dressed weights of 10.5 kilograms, and fat and oil weights of 1.4 kilograms, for a dressing percentage of 46.9 percent. The former had a live weight averaging 50.9 percent more than the latter, a dressed weight averaging 60 percent higher, an oil and fat weight 92.86 percent higher, and a dressing percentage 3 percent higher.

Nowadays the people of many country's in the world want and favor the meat of young animals rather than that of adult animals, and the demand for lamb and kid is particularly noticeable. As a result the price of lamb and kid on the international market is double that for goat and mutton. In addition to the aforementioned meat characteristics, because of the rapid growth of lambs and kids in the first several months following birth, their efficiency in using vegetable protein feeds is from half to double that of adult sheep and goats. Raising of lambs and kids requires only their mother's milk and pasturing on grassland, with no feeding or little feeding of concentrated feeds. Animals slaughtered before the onset of winter means a saving both in fodder, feed and work, and also prevention of deterioration by the following spring; it lowers costs, increases the return from feed, and has many economic benefits. In addition, the valuable pelts in the sheep raising industry generally come from the young of between 6 and 9 months old. It is precisely for this reason that some countries advanced in the raising of sheep have entered into specialized production of fatted lambs (6 to 9-month old lambs that have been fattened are called fatted lambs). In New Zealand, for example, 73.7 percent of all the sheep slaughtered in 1975 were fatted lambs, and exports of lamb were 3 times that of mutton. Australia's 1974 output of fatted lamb amounted to 61.6 percent of total output of lamb and mutton. In the American market, lamb and fatted lamb account for 94 percent of total sales of lamb and mutton.

Mutton and goat are important meats eaten by China's people, and they are the principal meat eaten by many national minority peoples in particular. Gansu Province's average consumption of mutton and goat is not great, and one might say that mutton and goat are truly rarities. If a portion or most of the province's almost 4 million head of goats were to be improved through hybridization, the hybrid ewe's used to supply milk, and the bucks castrated and slaughtered for their meat in the same year, not only would this help raise the people's nutritional levels, but it would also increase the earnings of the broad masses of herdsmen. This is a new way to produce lamb and kid meat, which should arouse the serious attention of units and leaders concerned.

PROPER MANAGEMENT TO INCREASE WINTER CROP PRODUCTION

Guangzhou NANFANG RIBAO in Chinese 14 Feb 82 p 1

[Text] Zhanjiang Prefecture Strives To Reap Bumper Harvest in Winter Yams

The majority of the communes and brigades in Zhanjiang Prefecture suffered considerable losses in grain production during the latter part of last year as a result of floods. In order to make up for the loss caused by the disaster and to tide over the lean months in spring, the various counties mobilized the masses to engage in the production of winter crops. Throughout the prefecture, 2.761 million mu of land was planted to winter sown crops, or 308,000 mu more than the previous year. Of this acreage, 1.92 million mu was planted to such grain crops as winter yam, or 157,000 mu more than the previous year. In Yangchun County, which had suffered heavy damage, 120,000 mu was planted to winter grain crops, or twice the acreage for the previous year. Up to the present, fertilizers have been applied once or twice to winter yams throughout the prefecture and the soil has been reconditioned. The yams are thriving and a bumper harvest may be expected.

Winter Sown Wheat Thrives Well in Chao'an County

In Chao'an County this year, 97,500 mu of winter sown wheat has been planted, an increase of 46 percent over the figure for last year. The wheat is thriving well because it was planted early and was well managed.

In the planting of winter wheat in Chao'an County this year, a superior variety of seeds was used, base fertilizers were applied before planting and the soil was tended with care. Furthermore, the seeds were sown from 7 to 10 days earlier than in previous years. In view of the short span which characterizes the fertilization and the growth period of wheat in the various areas, tillering fertilizers [0433 5649 5142] were applied and reapplied during the early stage to promote its early growth. Fertilizers to strengthen roots and stalks were skillfully applied in the intermediate and late stages. At the same time, water was applied scientifically, a forecast was made of insect pests, chemical weed killers were used extensively, and insects and rats were exterminated to ensure the normal growth of wheat.

Wuhua County Does Well in Tobacco Production

Wuhua County, taking advantage of the winter lull and making use of arid areas, planted 31,100 mu of tobacco last winter.

In order to do a good job in tabacco production, the concerned departments in the county paid attention to the implementation of the tobacco purchasing policy and signed a number of contracts for the sale and marketing of tobacco. The supply and marketing cooperatives of the county also organized 200 workers in tobacco production to go to the various farm families to instruct them on the planting of tobacco and the management of the operation. Benefiting from the lessons they had learned in the past of the extensive damage done to the tobacco seedlings due to frosts and the failure to take proper preventive measures, the various communes and brigades planted tobacco ahead of time last winter. When the tobacco was solidly rooted, fast-acting fertilizers were slowly applied. When winter frost came, antifrost covers were used, enabling the tobacco plants to survive and to flourish.

Shaoguan Prefecture Strengthens Rape Cultivation Management

Last winter, Shaoguan Prefecture, taking advantage of the winter lull, planted 393,000 mu of rape, or 10,000 mu more than the previous year. Yingde County, which has the largest acreage, planted 183,000 mu of rape, exceeding the quota set by the prefecture by 147 percent. Because various locations in the prefecture have implemented widely the production responsibility system of either assigning production to each household in return for fixed levies or fixing output quotas to individual able-bodied laborers, the enthusiasm on the part of the cadres and the masses for planting and managing the rape have been considerably heightened. The three brigades of Banpu, Boxia and Sanjiaokeng of the Qiaotou Commune in Yingde County, taking advantage of the winter lull, planted rape with planted areas reaching 7,000 mu. Since the enforcement of the production responsibility system, commune members attended to their duties assiduously, applied adequate amounts of fertilizers before planting and erected bamboo fences along the roadsides to prevent the animlas from trampling on the vegetables. At the present time, winter sown crops in the farmland of many areas in Northern Guangdong are doing extremely well.

BAMBOO CAGE FISHING IN RESERVOIRS DEVELOPED

Guangzhou NANFANG RIBAO in Chinese 9 Feb 82 p 2

[Article: "Thirty-five Counties in Guangdong Develop Fishing in Reservoirs"]

[Text] Since 1977, 35 counties in our province have launched a drive to use bamboo cages for fishing in 79 reservoirs with promising results. The cages are hoisted every day or every few days. The catch usually ranges from several hundred to 10,000 jin. The cost is 50 to 80 percent lower than that of using other fishing gear.

Previously, fishing in reservoirs was done mostly by using gill nets, trawl nets, electricity and by draining the reservoirs. High in cost and low in productivity, these methods do great damage to resources. Furthermore, because too large a quantity of fish is caught within too short a period of time, the rate of spoilage is high. In 1973, the Zhujiang Marine Products Research Institute, working on the principle of using nets made of bamboo slats for fishing, devised a trap in the shape of a cage measuring 40 meters in length and from 5 to 10 meters in height and width. The point of entry is shaped like a trumpet while a funnel-shaped net is fixed to the throat, making it easy for the fish to get in and difficult to get out. When this device had its test run at the Shahe Reservoir in Kaiping County, the comrades at the reservoir discovered that after a school of fish had entered the funnel-shaped net, it became so congested that a number of fish turned tail and escaped. Thereupon, the comrades at the reservoir affixed a tapered net at the point of entry so that once they had entered the net, the fish were ready to be taken.

The best time for using this type of net for fishing is from April to October when it is warm and rainy and when the fish customarily go upstream in search of food or to look for spawning grounds before going back downstream to rest. By placing this type of net where the fish make their return run or where they go in search of food, it would not be necessary to drive them into the net or to assign somebody to watch them, since the fish would enter the net of their own accord. The net is raised every day or every few days. This operation requires two boats and from two to four workers to haul in the nets. If necessary, the cage-shaped nets may also be used as casting nets.

MAKING NEEDED MATERIALS AVAILABLE TO PEASANTS NOTED

Guangzhou NANFANG RIBAO in Chinese 2 Feb 82 p 2

[Article: "How the Industrial and Commercial Departments Can Meet the Peasants' Demand for Production Materials"]

[Text] At a recent meeting of the province on the supply of agricultural production materials, the managers of production companies from the various areas expressed the unanimous view that agricultural production had reached new heights in the rural areas, that the peasants had the money to buy urgently needed production materials, that the industrial and commercial departments must pay serious attention to this new situation and that they must make available to the peasants production materials as well as consumer goods.

According to the findings of the concerned departments, the peasants are eager to spend the money they have to buy the production materials they need, especially those from areas where the agricultural production responsibility system was implemented at an early date and which have had bumper harvests. There is not only a sharp demand for production materials, but the size of the demand has also assumed increasing proportions. For example, the sale of agricultural production materials by the Lantang Commune in Zijin County totalled only some 390,000 yuan in 1979, whereas from January to September, 1981 alone, the sale of such goods exceeded 760,000 yuan. Among the production materials sold, the amount of chemical fertilizers doubled over that before the enforcement of the production responsibility system. Following the implementation of the system, the Chang [0960 1122] Commune in Lechang County bought some 9,600 pieces of medium and small-sized farm implements during the first eight months of last year whereas only 6,400 pieces were bought during the same period the previous year, showing an increase of 48 percent.

Another new development in the market for agricultural production materials is that the peasants are more concerned over the economic benefits of investing in production and in purchasing production materials, commonly demand that these materials be economicall and suitable and that they be of a high quality. There is, for instance, a sharp increase in the demand for chemical fertilizers. According to statistics, the use of chemical fertilizers on each mou of paddy field in areas where the application of fertilizers was already of a high level came to over 200 jin. Even in areas originally low in the usage of chemical fertilizers, the rate of usage has reached 80 or 90 jin, in general, an increase of 20 to 30 jin. There have also been new changes in the kind of fertilizers in demand, such as the demand for a larger supply of urea and potassium. In 1978, less than 20,000 tons of potassium were used in the province whereas in 1981, the amount had increased to 130,000 tons. In 1978, only 800,000 tons of phosphate were used whereas in 1981, the tonnage had reached 920,000. There has also been a greater demand for a wider variety of medium and small-sized farm implements, such as dragon-bone water lifts, old-style threshing machines, one-man threshing machines and funnels, which had long fallen into disuse and have now become hot-selling items. Other new products such as plastic urinals and pots for seedlings are also in great demand by the peasants. As for oxen used for farming, the demand in some areas is for small oxen and buffaloes which sell for between 300 to 500 yuan and which are most suitable for exclusive use by single families because they can be used to till the land during the planting season and to carry burdens during the off season. In 1980, the Jiujiang Production Brigade of the Shihgu Commune in Gaozhou County had only 139 oxen for farming, but the number had increased to 350 in 1981. Over 80 percent of the farm families in the brigade have their own oxen for farming. Since the implementation of the production responsibility system, the work of making available agricultural production materials to the peasants has also undergone vast changes. Formerly, the major clients for agricultural production materials were the production brigades which were more centralized and whose distribution capacity is greater making the work of distribution much simpler. Now that thousands of families have to be served, more frequently, with a lesser volume of supplies, and in a shorter purchase time, the volume of work has greatly increased. For example, Shantou Prefecture originally had 2,008 fertilizer and farm chemical supply stations employing 3,800 salesmen. By 1981, the number of stations had increased to 3,000 and the number of salesmen to 4,500. And yet, during the busy farming season long lines were formed by the masses waiting to buy farm chemicals and fertilizers.

As regards the present situation in the market for agricultural production materials in the province, the supply of fertilizers has shown a considerable increase while the reduction in the supply of film used for farming is likely to create a shortage, especially in medium and small-sized wooden farm implements and boats used for farming. Due to the shortage of raw materials and pricing problems, the production and supply of such products are likely to continue their downward trend. The concerned departments at various levels must alert themselves to the seriousness of the problem and adopt appropriate measures to remedy the situation.

INCREASED EARNINGS FROM AGRICULTURAL, INDUSTRIAL DIVERSIFICATION REPORTED

Guangzhou NANFANG RIBAO in Chinese 20 Jan 82 pp 1, 3

[Article by Liang Fuqing [2733 4395 2348] and Tao Guangyuan [7118 0342 0337]: "Great Increases in Collective Distributions in Foshan Prefecture in Year of Major Disasters. Sunlight from Third Plenary Session Illuminates Pearl River Delta. Average Annual per Capita Collective Distributions at 39 Yuan for Past 3 Years, While During 11 Years Prior to the Third Plenary Session Annual per Capita Increases in Earnings Only 2 Yuan. Ever Increasing Contributions to Country; More and More Commodities Provided Society"]

[Text] The year 1981 was one of disasters for Foshan Prefecture, yet it was a record year for distributions from collectives. The prefecture's average distributions per capita rose from 199 yuan in 1980 to 231 yuan.

In the 3 years since the Third Plenary Session [of the 11th Party Central Committee], Foshan Prefecture's principal agricultural products--rice, sugarcane, peanuts and pond fish--rose from a pre-Third Plenary Session average annual rate of increase over a 12-year period of 0.8, 3.1, 10.1 and 3.1 percent respectively to 13, 16.8, 31.7 and 6.6 percent respectively. The prefecture made an increasingly great contribution to the country, and provided ever larger amounts of commodities to society. During the last 3 years the prefecture's rural collective distributions have averaged an annual per capita increase of 39 yuan, while in the 12-year period prior to the Third Plenary Session, annual per capita increase averaged only 2 yuan.

Consecutive years of increased output and increased earnings have made the lives of local peasants increasingly rich and varied. In 1981, more than 84,000 commune member households in the prefecture built new houses. The rural population drinking running water rather than water from rivers increased by more than 360,000. Commune member savings deposits (as of the end of 1981) amounted to 760 million yuan. These were all-time records. A substantial number of households had savings of 10,000 yuan. Xiaolan Commune in Zhongshan County had more than 500 such households, and Guzhen Commune had more than 300.

Following the Third Plenary Session and under the guidance of national plans, Foshan Prefecture respected the self-determination of production teams, and adapted general methods to local situations in a production program of gradual all-around development of farming, forestry, animal husbandry, sideline occupations and fisheries, which changed the substantially singular former economic structure of agriculture and created conditions for consecutive years of increased output and increased earnings. As a result of small area experiments conducted during 1979 and 1980 in growing crops other than paddy rice (sugarcane and peanuts), and inasmuch as a bumper rice crop had been harvested during those 2 years and a substantial amount of grain was in storage, in 1981 the prefecture converted 5 percent of its paddyfield area (slightly more than 240,000 mu) to the growing of sugarcane and peanuts, or dug ponds to raise fish. Most of these paddyfields were low-lying fields, brackish fields, windy coastal fields or rather arid hilly fields whose output of rice was very low and whose economic benefits clearly increased as a result of the conversion. Calculated on the basis of prevailing award sales policies for sugarcane and pondfish, as a result of the prefecture's 1981 expansion of the growing area and increases in yields per unit of area, increased earnings from sugarcane may amount to 84 million yuan. Output value of pondfish increased by more than 20 million yuan.

Foshan Prefecture's production program for all-around development of agriculture not only did not weaken but rather promoted grain production. The role of rotational cropping of rice and sugarcane and rice and pulses was particularly striking. As compared with the 12 years prior to the Third Plenary Session, 1980's output of more than 5.6 billion jin of rice was 450 million jin more than the 1977 all-time record. Output in 1979 also surpassed that of every year save 1977. The 1981 early and late rice crops were seriously hit by five water or wind disasters, and output fell by more than 1 billion jin from that of the previous year; nevertheless, it was still clearly greater than the era of "take grain as the only link."

One important aspect of Foshan Prefecture's multiple operations and all-around development of agriculture was the full use made of abundant local resources, of its proximity to Guangzhou, Hong Kong and Macao, and its fairly well developed commodity economy for active development of commune and brigade enterprises to increase peasant earnings. With the encouragement of a series of correct policy measures pertaining to production, supply and marketing, during the last 3 years average annual increases in earnings of the prefecture's commune and brigade operated enterprises rose from somewhat more than 26 million yuan and somewhat more than 23 million yuan respectively for the 12 years prior to the Third Plenary Session, to somewhat more than 190 million yuan and 107 million yuan respectively. In 1981, in particular, with implementation of special economic policies, earnings of commune "three intake and one supplement" enterprises in the prefecture increased by 62 percent over 1979. In response to the people's building of large numbers of new houses in cities and the countryside, and to the need for high quality goods for use in their daily lives, commune and brigade enterprises that developed most rapidly in 1981 were those that produced light industrial goods, and beverage processing industries, including those producing building materials, electric fans, embroideries, high quality furniture, small hardware items, and on down. Gross earnings for commune and brigade enterprises during 1981 are estimated at more than 1.7 billion yuan, which is 78 percent of the prefecture's gross output value from agriculture.

NEW IMPETUS TO SUGARCANE PRODUCTION IN PANYU COUNTY REPORTED

Guangzhou NANFANG RIBAO in Chinese 30 Jan 82 p 1

[Article: "Panyu County Province Champion in Sugarcane Output. Despite Grain Output Reduction in 1981, Average per Capita Income Showed Slight Increase"]

[Text] As a result of needed readjustment of the structure of agriculture during the past three years, Panyu County has become one of the province's major cane sugar production bases. The county holds first position in sugarcane growing area, total output and yields per unit of area. It is estimated that in 1981 output of the county's sugarcane industry may reach more than 1.45 million tons, and that yields per unit of area will be 6.3 tons, for increases over 1980 of 30 and 1.6 percent respectively.

Paddy rice and sugarcane have always been Panyu County's two major crops. However, because of past one-sidedness in the guiding mentality, sugarcane production developed rather slowly. During the 1960's and up until the mid-1970's, the sugarcane growing area hovered around 130,000 mu; output totaled no more than about 500,000 tons; and yields per unit of area were somewhat more than 3 tons, lagging far behind the major sugarcane producing areas of Shunde and Zhongshan counties. In 1977, and particularly following the 3rd Plenary Session [of the 11th Party Central Committee], acting on the basis of local suitability for the growing of sugarcane and under guidance of the state plan, the county gradually increased its sugarcane growing area annually while maintaining steady growth in grain output. By 1981 the sugarcane growing area had increased to 230,500 mu, which was 34 percent of the county's cultivated land area.

In 1981 the county sustained natural disasters and, furthermore, because a system of responsibility for production had not been completely implemented at the time of the early rice crop, grain output dropped by 120 million jin from the all-time high year of 1980, yet maintained the bumper harvest level of 1977. Now the county has substantially fulfilled its public grain quotas. Despite the reduction in grain output, because of the bumper harvest in sugarcane, average per capita distributions in the county showed a slight increase over the 276 yuan of 1980.

BRIEFS

RUBBER OUTPUT UP--The Tongshi State Farm and Land Reclamation System has sent an encouraging victory report. In 1981 the reclamation area was hit with a 5-force typhoon, but after more than 3 million slashed rubber trees were snapped off, the broad masses of staff and workers in the state farm and land reclamation area roused their revolutionary spirit to triumph over post-disaster hardships and rapidly restore production, winning a bumper rubber output in a disaster year. Last year's output of 31,200 tons of dry rubber overfulfilled by 204 tons the annual state plan. Nantian, Nanmao and Sandao farms, which were hardest hit in 1981, handled the wind damaged trees within a short period of time and cleared away roads in the rubber tree groves, collected broken off rubber tree timber, remedied post-disaster damage, and rapidly restored production. In addition, all farms intensified scientific care of damaged trees, nurtured rubber output potential by applying technical regulations, bringing some wind-damaged rubber trees back into production ahead of schedule to increase dry rubber output and assure fulfillment of state production plans. NEW HYBRID RICE--In order to hasten breeding of a successor variety to "Guichao," 22 agricultural science units in Guangdong Province's prefectures and municipalities began cooperation on 2 February on intermediate experiments with large area growing of new fine variety paddy rice, "Shuanggui No 1." Fine variety "Guichao," the renowned high-yield fine variety rice bred in Guangdong Province, has played a very great role in increasing grain yields since its promotion in 1978. However, as a result of having been planted in numerous crops over many consecutive years, this variety's resistance has gradually weakened. In the breeding of "Shuanggui No 1," the Multiple Genetic Techniques Breeding Research Office of the Rice Institute of the Provincial Academy of Agricultural Sciences crossed "Guiyang C 17," the female parent, with "Guichao No 2," the male parent, for the initial breeding in 1979 of a new fine variety, which can be used as either an early or a late crop. Testing at many sites has shown it to have short stems, tolerance of fertilizer, high yields, resistance to lodging, and a stronger resistance to bacterial blight and blast of rice than "Guichao No 2." Quality of husked rice is also rather good. This intermediate testing was done provincewide at 22 intermediate test sites of various kinds in mountains, hills and plains. At each site, demonstrations were conducted on 100 mu tracts, and some auxiliary experiments in culturing were also done. Before and after the lunar new year, all locales continued to run technical training courses. [Text] [Guangzhou NANFANG RIBAO in Chinese 6 Feb 82 p 1] 9432

SYSTEMS OF RESPONSIBILITY SAID TO NEED CORRECTION

Shijiazhuang HEBEI RIBAO in Chinese 1 Feb 82 p 1

[Article: "Zhangjiakou Prefecture Acts To Perfect Systems of Responsibility. Rapid Implementation, Persistent Consolidation, and Gradual Perfection"]

[Excerpt] Recently the Zhangjiakou Prefecture CCP Committee and provincial administrative offices convened a prefectural conference for exchange of experiences on systems of responsibility for agricultural production. Everyone referred to vivid realities to enthusiastically extol the systems of responsibility for agricultural production. Discussions linked to local realities brought forth ideas for perfecting systems of responsibility for agricultural production in 1982.

Since mid-August 1981, every place in the prefecture has been assigned by the Prefecture CCP Committee to use a guiding mentality of criticism of "leftism" to eradicate pernicious influences and of bringing order out of chaos in renewed study and implementation of the spirit of the 3rd Plenary Session of the 11th Party Central Committee, in running make-up classes for discussion of the issue of standards for truth, in redressing past wrongs on a wide scale, with the Hu Ge solution of problems being representative, and carrying out wide-ranging discussions of systems of responsibility for production. This has been for the purpose of breaking the fetters of erroneous leftist ideology and to clear away all obstacles for carrying out perfection of systems of responsibility for production, implementation work for the prefecture's systems of responsibility for agricultural production thereby developing fairly rapidly. As of now, 20,996 basic accounting units in the prefecture have set up various forms of a system of responsibility for production, of which 93.79 percent either contract production to households or contract work tasks to households under unified management. In the process of implementing systems of responsibility for production, inasmuch as some cadres lacked an accurate perception and had insufficient experience, some problems occurred. For example, in some units such problems occurred as making no distinctions between what belongs to one and what belongs to another, complete dividing up of everything, including cutting down trees, tearing down houses, and disposing of public property at low prices. In some other communes and brigades there existed the problem of one-sidedness in handling the relative interests of the state, the collective, and individuals. In view of these problems, the following four actions were proposed for improvements in systems of responsibility for agricultural production in 1982.

(1) Correct handling of the relationship among the state, the collective, and individuals. Regardless of the form of a system of responsibility practiced, provisions must first be made for, and fulfillment guaranteed for, state requisition procurement of grain and edible oils, quota purchases of agricultural products, and collection of revenues. As the peasants prosper, support for the party and the country cannot be forgotten, but rather necessary contributions to the country should be actively made. Furthermore, with the growth of production and the year-by-year increase in commune member earnings, public accumulations should gradually increase. Even production teams that practice contracting work tasks to individual households must withhold a certain amount, as resources permit, for public accumulation funds, public welfare funds, for strengthening the collective economy, and for developing collective endeavors.

(2) Correct implementation of the principle of doing in a unified way whatever should be done in a unified way, and contracting whatever should be contracted to protect and develop productivity. It is recommended that "contracting" be done under "unified" leadership, and that the "contracted for" should also be managed. Whatever should be unified and whatever should be contracted, or how things should be unified and how they should be contracted should have as their point of departure that which is both advantageous in protecting and developing productivity and in making the most of the superiority of the collective economy, and that which is advantageous in arousing the enthusiasm of the broad masses of commune members for labor, the emphasis being on the word "adaptation" in the adaptation of general methods to local situations, to times, and to industries. Persuasion of the masses has to be done on the issue of unifying and contracting, those things that should be unified being definitely unified, as for example, large farm machines and implements, fixed assets, and public accumulations, all of which should be unified. Orchards, large water conduits and such production facilities should be unified. When major natural disasters occur, in order that collective strength be brought to bear in carrying out a struggle against disaster, work forces must be planned and assigned in a unified way. In the case of those things that were divided when they should not have been divided, thereby damaging productivity, leaders at all levels should dare to get to work in restoring them to their original condition. In some places where draft animals, small water conservancy facilities, small farm implements and small production items are suitable for division among households for use and care, action should proceed from realities and dispersed use and care practiced.

MEASURES TO INCREASE HOG RAISING OUTLINED

Shijiazhuang HEBEI RIBAO in Chinese 1 Feb 82 p 1

[Article by Correspondent Li Lianyin [2621 6647 0603]: "Need for Speedy Reversal of Live Hog Decline"]

[Text] Editorial Department:

Recently I conducted an investigation on the issue of live hog production with concerned units in Langfang Prefecture. Results of the investigation showed that during the past 3 years the overall situation in live hog production in this prefecture has been that of a dramatic decline in collective raising of live hogs and not very fast development of private hog raising. Statistics as of the end of December 1981 show 709,834 live hogs in inventory in the prefecture, a 153,156 reduction from the same period in 1980, which is a 7.7 percent decline or a 52.4 percent decline from the all-time high. Why has hog production declined so drastically? Reasons are many, but it was caused mostly by lack of vigorous leadership, numerous policy changes and "difficulties in selling hogs."

How can decline in hog production be reversed? First it is necessary to study the new situations in agriculture following institution of systems of responsibility, and to strengthen leadership of the pig raising industry. Following the 3rd Plenary Session of the 11th Party Central Committee, this prefecture has corrected the former leftist ideology of taking hogs as the key link, and the breeding industry has flourished. However, when some leadership cadres have encountered new contradictions and new problems in the raising of hogs, they have not promptly studied and solved them. Some have even abandoned leadership of the hog raising industry, one-sidedly supposing that now that the land had been contracted to individual households, hog raising was a matter for individual commune members. In some communes and brigades a situation has emerged in which no one takes charge of the collective raising of hogs, and no support is given individual raising of hogs, so that hog raising is virtually in a state of limbo. In some production teams that practice a system of responsibility of "double contracting," collective hog raising has been entirely dispensed with. Now, the Langfang Prefecture CCP Committee and provincial administrative offices are emphasizing taking hog raising in hand as a mainstay project in rural economic diversification, reviving the former workable and effective management methods and administrative organizations, again designating special people to take charge of hog raising, and establishing a system of economic responsibility. In addition, they are also preparing to help some communes and brigades with proper conditions to establish commodity hog bases and shoat breeding bases, for a continuation of the practice whereby brigades do the breeding and households do the raising to get results in a short period of time.

Second is the consolidation of policies relating to bonuses and award sales for raising hogs to encourage collectives and individuals to raise more and sell more. In 1981 a substantial number of production brigades and production teams lowered bonus standards and eliminated the bonus system, and limited hog raising on the basis of population, which dampened the enthusiasm of the masses for hog raising. In 1981, households in the prefectures raising no hogs rose from somewhat more than 60,000 in 1980 to 110,000, lowering the amount of hog raising in the prefecture as a whole. In Dacheng County, 69 percent of production brigades and 77 percent of production teams abolished their policy of issuing bonuses for hog raising. Bonus grain and bonus workpoints issued for summer hog raising in the county amounted to only 13 percent of the 1980 amount. As a result, as of the end of 1981, hogs in inventory had declined 12,350 head from 1980. This situation has aroused the serious concern of the Langfang Prefecture CCP Committee and government administrative offices, who have renewed and formulated bonuses and award sales for hog raising. They have made a special point of protecting hog breeding and have implemented these measures quickly in order to win the confidence of the people.

Third is clearing of circulation channels to help commune members sell their hogs. Since 1979, this prefecture has had "difficulties in selling hogs" during June, July and August. Because prefectural units concerned instituted a system whereby procurement quotas were set on the basis of sales, many fattened hogs that should have been sold did not sell. In Xianghe County, from 1 June onward, live hog procurement points were reduced from 17 to 7, and a limit of 20 head procured each day was set. This restriction remained in force until October. This resulted in a loss of hogs to other areas or keeping them in sties, creating economic losses for the country, the collective and individuals, and impairing the enthusiasm of the masses for hog raising. Beginning in the fourth quarter of 1981, prefecture and county live hog procurement units used all possible means to solve the problem of "difficulties in selling hogs." Taking in hand both procurement and sales, with the help of the concerned provincial units, they several times consulted with and signed agreements with Beijing and Tianjin markets. This year they are preparing to overpurchase live hogs, and the problem of "difficulties in selling hogs" should be substantially solved. In addition, all counties are to revive their former live hog procurement points to help the masses sell their hogs nearby for a steady expansion of city and country markets for sales.

SCIENTIFIC FARMING METHODS PRODUCE BUMPER YIELDS IN TEST FIELDS

Beijing GUANGMING RIBAO in Chinese 14 Feb 82 p 2

[Article by Lin Yutang [5677 3768 1016] and Lu Shiqi [7627 1102 3444]: "Science Has Entered the Responsibility Fields; Grain and Cotton Has Increased and Earnings Are Greater. Bumper Yields Harvested from 600,000 Mu of Multiple Demonstration Fields in Hebei Province; Economic Benefits 25 Times Greater Than Investment in Technology"]

[Text] Recently the Hebei Provincial Science Commission decided to enlarge and spread agricultural technology demonstration fields this year. Last year, acting on the basis of different natural conditions in individual areas, the Provincial Science Commission adapted general methods to local conditions in 22 counties to lay out 600,000 mu of demonstration fields for promotion of multiple agricultural techniques, prompting 45 new agricultural techniques and new achievements. Despite continuance of unfavorable climatic conditions including drought, low temperatures, and early frost, bumper yields of grain, cotton, oil-bearing crops, and fruits were harvested. Comparison with control fields having the same water and fertilizer conditions showed 20 to 30 percent yield increases, and economic benefits equivalent to 25 times the technological investment.

Jimian No 2 and Lumian No 1, two new cotton varieties, were extended to cultivation on 188,200 mu of cottonfields in 9 counties including Zhengding, Yongnian, Hejian, and Gucheng, and use of new pesticides and chemical ripeners, scientific care, and skillful watering and fertilization during crucial periods of growth were also promoted as part of 12 new techniques. Yields per mu averaged increases of from 23 to 25 percent as compared with control fields. Following a general soil survey, Sanhe County focused on the soil's serious lack of phosphate, promoting new techniques in scientific fertilization with phosphate on 140,000 mu of land in 8 communes for wheat yields averaging increases of from 64 to 95 jin.

Last year Funing County suffered serious drought. On 20,000 mu of paddyfields they promoted early seedling propagation, shallow plowing, chemical weeding, restructuring of fine varieties, and such new techniques. In a year of great drought, paddy rice yields averaged yields of 961 jin per mu, a 19.2 percent increase in yields over control fields. Net earnings amounted to 7.6 times the investment in technology.

Qing County, located in the Hai He basin, has more than 300,000 mu of saline-alkaline soil on which formerly only grain was grown, producing yields averaging no more than 100 jin per mu. They summarized experiences with test plantings of sunflowers during the past several years, and promoted planting of 20,000 my of saline-alkaline land to new varieties of sunflowers that tolerate salinity and alkalinity, tolerate drought, and have high economic value as well. They also spread new techniques of sowing seeds at the right time so that the period of flowering would miss the rainy season, the pollination rate being increased thereby for sunflower seed yields of 152 jin per mu and economic benefits from 3 to 4 times those obtained from the growing of grain.

NUNJIANG ADHERES TO STATE PLAN IN CROP PRODUCTION

Harbin HEILONGJIANG RIBAO in Chinese 22 Feb 82 p 1

[Article: "Nunjiang Prefecture Maintains the Proper Ratio Between Grain and Cash Crop Production According to the State Plan"]

[Text] Acting under the guidance of the state plan and strictly adhering to the ratio for the planting of grain and cash crops, Nunjiang Prefecture has been able to increase both production and income, to produce food as well as a profit, and to meet overall as well as local needs.

An important food production area, Nunjiang is also well suited for the development of such cash crops as sugar beets and sunflower. Under the erstwhile "leftist" influence for a long period of time, Nunjiang had caused a serious imbalance in the agricultural situation by putting too much emphasis on food production. Since the Third Plenary Session of the 11th Party Central Committee, however, Nunjiang has reversed its position of putting emphasis on grain production and has correctly readjusted its agricultural economic system in accordance with the policy of "not relaxing efforts to develop food production, but developing diversified operations in a positive manner." By 1981, Nunjiang had increased the acreage for cash crops to 3.21 million mu, an increase of 1.71 million mu over the acreage for 1979, or 14.3 percent of the acreage of the cultivated land. By the end of the year, food production had increased by 16 percent compared to the figure for the previous year; the amount of grain for exchange purposes had increased by 15.3 percent; and cash crops showed a further increase over the figure for 1979, on top of the increase of 70 percent for 1980. The average collective income for each commune member came to 126.7 yuan, the highest ever recorded.

While setting the proper ratio for the planting of grain and cash crops for this year and combating the tendency on the part of certain cadres in the production teams to favor the planting of a variety of cash crops for profit, Nunjiang Prefecture made it very clear that while it is wrong to place emphasis exclusively on grain production, it is also wrong to overlook its importance, let alone to neglect the production of grain for the sake of making a profit. While the nation is still plagued by a shortage of grain, efforts should be made to remedy the shortage. The overplanting of sunflower by some production teams last year has had an adverse effect on grain production. While drawing up plans for agricultural production for 1982, the party committee in Nunjiang proposed that the production teams should reduce to a reasonable level the acreage planted in sunflower, should set the acreage for the planting of grain and cash crops for the entire area, and should maintain the existing level during the next few years. It is only when there is agreement among the production teams on how readjustments should be made on the basis of actual circumstances, such as permitting impoverished production teams to engage in the planting of cash crops, that the situation of impoverishment can be brought to a speedy end.

Under the guidance of the state plan, efforts should be made to approach the matter of planting in a logical manner, to set up a reasonable ratio for the planting of grain and cash crops, and to increase the rate of profits from the available acreage. The relevant departments in the prefecture should assist the commune production teams and commune members in the various counties to dedicate themselves to the establishment and perfection of the various forms of the production responsibility system, to strengthen the administration of operations, and to develop fully the positive attitude of the communes collectively and the commune members individually. In the production of cash crops, efforts should also be made to organize professional teams, professional units, professional families, and professional individuals; to put into practice the responsibility system of paying each according to his work; and to strengthen the administration of cash crop production.

PREPARATIONS FOR A NEW YEAR OF FARMING URGED

Shenyang LIAONING RIBAO in Chinese 19 Feb 82 p 1

[Article: "Earnestly Do a Good Job of Spring Farming and Grain Production. Provincial CCP Committee and Provincial Government Issue Instructions"]

[Text] The lunar new year has passed and the busy season of spring farming and production will soon be here. So that greater development will take place in Liaoning Province's agricultural production this year, all levels of CCP committees and government, as well as the braod masses, should immediately act and nor lose the opportunity to prepare to farm, and to do spring farming and production.

1. There should be diligent implementation of the summary of minutes of the national rural work conference, and further perfection and implementation of production responsibility systems. As of now an overwhelming majority of communes and brigades in the province have instituted production responsibility systems, which require consolidation and no further changes. Where responsibility systems have not been implemented, discussions should be held with the masses. If views differ, there can be full discussion, the forms of responsibility systems about which an overwhelming majority of commune members agree being selected and put into operation as quickly as possible.

Agricultural production should continue to adhere to program of taking the planned economy as the key link, with market regulation being supplementary. All jurisdictions should rapidly institute agricultural production planning. Brigade and commune cadres as well as commune members should be indoctrinated in obedience to state plans, attention given to surmounting and correcting situations of separation from state plan guidance. However, there should be no recurrence of the former old defect of stultifying uniformity at the mere mention of obedience to state plans. Joint discussions and signing of state purchase and quota purchase contracts between the state and collectives or individual commune members are concrete embodiments of taking the planned economy as the key link and obedience to state plans. If only collectives or commune members fulfill state purchase and quota purchase contracts, it will not be necesaary for the state to interfere excessively, and portions that collectives or individual commune members are permitted to work will be given active help.

2. While assuring steady increase in grain production, it is necessary to actively launch economic diversification, promoting the all-around development of farming, forestry, livestock raising, sideline enterprises, and fisheries. Following several years of readjustment the province's agricultural crop patterns tend to be equitable in the main, requiring no further changes. The key to development of grain and economic crops lies in increase in yields per unit of area. Except for individual places in which proper readjustment has not yet been made, the area sown to grain should mostly be maintained as it is with no further reduction. Close-in suburbs should take vegetable production as the key link, and diligently do a good job of vegetable production. It is necessary to make equitable use of various resources, broaden production avenues, and actively develop economic diversification into forestry, livestock raising, sideline occupations, fisheries, and industry. Clearing of land for agriculture on mountain slopes and pastoral area grasslands is to be strictly prohibited, and those destroying resources or water and soil conservation are to be dealt with severely.

3. Need for strict attention to combat against drought and preservation of soil moisture to assure timely sowing. The western part of Liaoning Province has had 2 consecutive years of drought and the soil is seriously devoid of moisture. In other areas too, because of the scant rain and snow last fall and winter, a spring drought will take place. In the central Huntai region of Liaoning, reservoir water storage is 330 million cubic meters less than for the same period last year. It is the year of least water storage since 1979. Triumph over drought and the scarcity of water have become key problems in most parts of the province in deciding whether planting can be done on time. All locales should fully realize this and take resolute measures to do a good job of combat against drought, make full use of existing water sources for spring irrigation, do a good job of raking and compacting to conserve soil moisture, do plowing and ridging [in early spring when soil moisture is at the highest point], rush plant to take advantage of soil moisture, and assure prompt sowing of seeds. Combat against drought must both be taken firmly in hand and also proceed from realities, with striving for economic benefits, adaptation of general methods to local situations, and sensible arrangements. Some seeds must also be set aside for late planting of fields. Central region wetland areas should adopt effective measures for planned use of water, equitable use of water, conservation in the use of water, and for development of sources and restriction of flow. They should make full use of existing pump wells, but should strictly control the addition of new wetlands. They should actively spread the successful experiences of many years in combating drought on wetlands, strive to plant wetland fields at once, and take good care of them. Low-lying areas prone to waterlogging should organize forces to build terraces, and to clear silt from ditches along field rows and from drainage and irrigation ditches.

4. Diligent attention to spring farming and production materials preparation work. This year a shortage of fertilizer continues in the province, and phosphate fertilizer is very scarce. All locales should direct serious attention to this matter. They should arouse and organize the masses for vigorous development of a campaign to accumulate farmyard manure. The

industrial sector should do everything possible to produce more chemical fertilizer, plastic sheeting, and highly effective pesticides of low residual toxicity. Attention should be devoted to organization of units concerned to manufacture and promptly supply small farm tools. A good job should be done of selecting seeds and of transfering surpluses to places having shortages, to livestock innoculations, to springtime afforestation, and to inspection and repair of fishing boats and nets. Farm machinery should be promptly inspected and repaired. Responsibility systems for farm machinery linking output to calculation of compensation should be rapidly established, and key mechanized production brigades set up. This year should bring new breakthroughs in the sowing of seeds, the transplanting of seedlings, cultivation and weeding, prevention and control of diseases and insect pests, and in combat against disasters. Commercial, supply and marketing, and banking units should promptly supply the materials and the credit needed for spring farming and production work.

5. Science and technology should be vigorously popularized and spread, and action to increase agricultural production vigorously taken. All jurisdictions should respond to the new situation of urgent demands by the broad masses of peasants to study science and to use science, and adopt various methods of popularizing agricultural scientific knowledge for all-around improvement in the level of agricultural production techniques. Existing scientific and technical accomplishments should be spread, and advanced scientific and technical accomplishments should be translated into direct productivity. Places and stations for the promotion of technology having requisite conditions can set up technical contract agreement systems with production teams, organizations, and specialized households. During the stage of preparing to farm, level by level peasant technical mainstay cadre training classes should be run to summarize and promote science and technology and advanced experiences in farming, forestry, livestock raising, sideline occupations, and fisheries to meet this year's needs for all-around development of agricultural production.

6. Need to strengthen leadership of preparations for farming and spring farming work. Plans for the entire year depend on the springtime. The work of preparing for and doing spring farming directly relates to agricultural production for the entire year. All levels of the people's government must make preparation for farming and spring farming the central task in rural areas at the moment, and conscientiously strengthen leadership. All rural work should center around and be subordinate to preparation for farming, and spring farming and production. All levels of leadership cadres should go down to villages in order to promptly understand and solve problems in preparing for farming and spring farming. All trades and industries must support rural villages to do a good job of preparations for farming and spring farming. Disaster areas should closely link arrangements for the livelihood of the masses with preparations for farming and spring farming and production. Cadres should be indoctrinated and the broad masses of people aroused to continue to go all out, to carry forward the fine work style of arduous struggle, and to do all work better than it has been done in previous years to win a greater bumper harvest in agricultural production this year.

FORESTRY SPECIALISTS ISSUE CALL TO SAVE FORESTS

Xian SHAANXI RIBAO in Chinese 22 Feb 82 pp 1, 2

[Text] A survey report, "Flood and Forestry", written by 20 specialists, professors, and scientists of forestry, water conservancy, and environmental protection provides facts to prove that the destruction of forest vegetative cover will lead to a loss of ecological balance, the deterioration of the environment, and endless after effects, and the extraordinarily severe flood of the western part of Qinba Mountains of Shaanxi serves to prove their point. In the report, the specialists made an urgent appeal to save the forests. They also offered a 5-point proposal regarding forestry construction.

This survey project was organized by the Provincial Bureau of Forestry and the Provincial Forestry Society. The report was written following an on-site inspection, survey, and interview tour of the flood damaged 8 counties and 1 city in Hanzhou and Baoji.

The Lower the Forest Cover, the More Severe is the Flood Disaster and the Greater are the Losses

The survey report states that the flood disaster of last year in the regions of Qinling and western Bashan takes the following form: In low hill areas of very few trees, aside from the destruction of some dwellings and lands along the banks of streams, the more serious situation is the severe erosion everywhere. Landslips, cave-ins, and mud-rock flows are the cause of disastrous losses of lives and properties. In Pingchuan Prefecture, the torrents rise and rivers overflow, the dikes break, and many farms and villages are inundated to result in gigantic economic losses. According to historical data, this flood is by no means the worst in history, however. On 26 July 1890, the Jialingjiang River rose suddenly in Lyueyang County to cause the county courthouse to be in 3 chi deep of water. A marker is still on the pillar to record the water level. The marker recording the current flood is 84 cm lower than the one in 1890. In Hanjiang, the greatest flow volume in 1964 was 5,650 m^3/sec and that of last year was only 4,810 m^3/sec. The frequency of floods in these 2 places has also been increased. Before the liberation, it was one flood every 28 years; now it averages once every 5 years.

Why is it that the flood is by no means the largest but the damage is so extraordinarily severe? Why is it that the frequency of floods has increased? The following comparative data are provided in the report:

Name of County	Rate of Forest Cover (%)	Rainfall From 1-25 August (mm)	Losses (10,000 yuan)
Taibai	77.8	509.6	2026
Liuba	58.8	572.0	1839
Fengxian	42.6	363.8	about 8000
Lyuyuang	31.6	627.5	5671
Ningqiang	26.1	528.0	8196

It may thus be observed that the rainfall is the direct reason for the disaster, but the extent of the disaster caused by the rain, the size of the loss, etc. are all closely related to the forest cover. The forest coverage is the highest in Taibai and Liuba counties, the rainfall was large, but the losses were the smallest. Lyueyang and Ningqiang counties are the opposite. Their forest coverage is the smallest, the rainfall is similar, but the losses are 1 to several times those of Taibai and Liuba.

Why do Mud-rock Flows and Landslips Run Wild?

From on site inspections, the specialists discovered that mud-rock flows and landslips of hillsides resulting from heavy rains are the major form of disaster in the mountain regions. According to incomplete statistics of the 5 counties of Mianxian, Lyueyang, Ningqiang, Nanzheng, and Liuba, mud-rock flows and landslips occurred more than 10,000 times. On 2 Sep last year, a giant landslip occurred in Minzhu Brigade No 4 of Changgouhe Commune, Mianxian, measuring 400 m in height and 300 m in width, amounting to 2 million m^3 of mud and stone. It came down so suddenly it buried 49 dwellings and destroyed 56 mu of fields. On the ground, the mud and stone pile became a large dam of 30 m in height, 200 m in width, and 250 m in length to block the water of the stream and to accumulate 100 thousand m^3 of water on top of 36 mu of fields to make that area into a reservoir.

Along the Fengzhou Section of the Baoji Railway, there were landslips in 92 places and in 44 places the roadbed was destroyed. Ten large and medium bridges were knocked down and 3 railway stations were buried. The operation of Baoji Railway was interrupted for as long as 2 months.

The survey report states that the complex geological structure of Qinling and Bashan, the steep mountain slopes, the great drop of ravines, and the very changeable terrain are all factors contributing to the easy occurrence of mud-rock flows and landslips. Last year's large storms is the natural factor which produces them, but the abusive logging practices of many years, the destruction of forests for cropping, and the disregard for water and soil conservation have led to the certainty of their occurrence and amplified their destructive force. When a large area of land loses its forest vegetation protection, the runoff on the mountain slopes pours down in a heavy rain to form swift streams to cut the land and dig up the slopes of ravines so that a localized body of the mountain loses balance and collapses into mud-rock flows and landslips. The report compares the relationship between vegetative cover and landslide in the various regions of Ningqiang County: In Daijiaba Region, the coverage is 32 percent, landslides occur in 2,966 places; in Yangping Region, the coverage is 32.6 percent, landslides occur in 1,273 places; in Tiezhen Region the coverage is 51 percent, landslides occur in 393 places; in Bashan Region, the coverage is 52.9 percent, landslides occur in 361 places. In Beiba, Zhongshan areas of Nanzheng County, the ancient granite has a weathered layer 2 m deep. This is where mud-rock flows can occur very easily, but the forest coverage is 62.3 percent and very little landslide occurs. On the road from Xiaoba to Xihe Commune, the specialists traveled more than 40 km and only saw 2 places of mild landslips. In the 690 thousand mu area, which is Beiba Forest, there was not a single dwelling destroyed by either landslides or torrents. According to the Department of Meteorology, the storm center was in the northwestern part of Sichuan and southeastern part of Gansu. It came down southward through Baishuijiang of Shaanxi to Lyuyang, Yangpingguan, and the southern part of Ningqiang before turning to Nanjiang County of Sichuan and the Beiba Region of Zhengxian County of Shaanxi. Fengxian of Baoji Prefecture is located outside of this boundary, but the condition of disaster is frightful. It is rather worst than Ningqiang, Lyueyang, and Mianxian. The specialists climbed up the Chaiguanling Range on the Baohan Highway and were able to observe the startling difference between the north and the south of the range. To the south, Zibai Mountain in Liuba County is covered densely with forests and almost no trace of flood damage is observable. To the north, in Fengxian County, landslips and mud-rock flows are everywhere.

Deforestation for Cropping Has Caused Erosion of Large Areas

The practice of destroying the forest and turning it into fields or enlarging the cropland through abusive reclamation is also an important reason for the flood disaster. The forests of the mountains of Qinling and Bashan have been repeatedly devastated by large area reclamation projects throughout history. After the liberation, the party and the government issued laws and orders to forbid destroying forests to crop the land but the practice has never been stopped. On the contrary, it is getting more and more devastating. According to the estimate of a related department in Hanzhong Prefecture, in these 30+ years, the reclaimed area is more than 2 million mu. After the forest vegetation is destroyed, large pieces of land are nakedly exposed. Every time it rains, the rain drops erode the soil and the runoff washes the soil away. Additionally, sloped cropland is less previous and can hardly store water. In this manner, a heavy rain causes a great disaster, and light rain causes a little disaster, and no rain causes a drought. Zhenba County is big in reclamation. From 1950 to 1980, 644,000 mu were thus reclaimed. The rainfall of Aug 81 was only 345 mm to make that county an area of very little rain in all of Hanzhong Prefecture, but 236,500 mu there were damaged and 20,000 mu of these were destroyed. The Aug rainfall last year in Liuba County was close to that of Ningqiang County, but 87 percent heavier than Zhenba County, but there has been very little reclamation and the forest coverage is as high as 75.6 percent; therefore, the damage is much milder.

With the increase of reclamation index, the area of sloped cropland is larger and the vegetative cover is poorer. Every storm flushes off a large quantity of mud and sand to add to the silt carrying quantity of the streams. According to the actual measurement records of the past 24 years of Wuzhen Hydrological Station of Mianxian, above Wuhouzhen of Mianxian, the Hanjiang River carries 2.49 million tons of silt a year on the average, reaching 8.66 million tons in the highest year. The annual erosion modulus is 804 ton/km^2 to 2,100 ton/km^2. Soil erosion of the Jialingjiang Valley is even more severe. According to an analysis of the 34-year data of Lyueyang Hydrological Station, Jialingjiang carries an average of 32.3 million tons of silt a year, 77.4 million tons in the highest year. The annual erosion modulus is 1,680 ton/km^2, 4,030 ton/km^2 in the highest year. This severe an erosion problem is comparable with the problem of the loessial plateau to the north of Huihe. The land is flushed to become thinner and thinner; the riverbed is silted to become higher and higher; and the flood disaster becomes more and more severe.

Five Proposals To Save the Forests

Specialists of the survey group point out: The Qinling Bashan region had once been in the past a place of trees and grass in profusion. The mountains were green and the waters were clear. There was no erosion. After the liberation, under the guidance of the party and the government, there was some afforestation efforts in areas of Hanzhong and Baoji but the force of historical tradition and the influence of the leftist errors caused terrible destruction of the forest vegetation. The forest ecological system of Qinling and Bashan could no longer withstand the attack. At present, the extent of erosion of this region is not yet as severe as that of the loessial region of northern Shaanxi, but the results are even more serious. This is due to the fact that in northern Shaanxi there is a thick layer of loess while in the region of Qinling and Bashan there is only a thin layer of soil. Once this layer is washed away, there will just be the bare rocks, difficult to change in thousands of years and the basic condition for agricultural production will have been lost. The specialists of the survey group, the professors, and the scientists are making this urgent appeal just for this reason. In their report, the following 5 proposals are also presented:

(1) The region of Qinling and Bashan are high mountains and steep slopes. The soil is rather thin and the geological structure is complex. This is one of the several areas of the country where mud-rock flows occur easily during storms. It is also the origin of several major streams, such as Jialingjiang and Hanjiang of the middle reaches of Changjiang. It is; therefore, necessary to forbid abusive logging to protect and manage the remaining forests. With management and reconstruction, the forest structure should be gradually reformed to improve its quality. There should be planned afforestation and renewal to nurture a forest reserve and to enlarge the forest coverage. The forest resources should be surveyed and the trees classified to provide a basis for designing a reasonable logging and utilization plan. Large area total logging and concentrated excessive harvesting should be prohibited.

(2) The ownership authority of the mountain forests should be clearly designated to reform the forest management system. For the State owned forests, forestry bureaus should be established according to a readjusted natural divisions to be managed by the provincial government in a unified manner. The current system of separation between the forest industry and the forest management must be changed. Harvesting, cultivation, and afforestation should be combined in the organizational structure and the management system. Forests belonging to the collectives should be managed by the forestry department of the prefecture or the county and there should be a unified and strict management system. There must be a procedure of granting permits before the communes, brigades, or their members are allowed to cut trees.

(3) Destroying forests for cropping should be strictly forbidden. The steep slopes must not be used for cultivating crops. Protection of the forest vegetation must be strengthened. There should be propaganda to teach the importance of preserving the ecological balance of nature. Those who destroy forests for cropping should be punished by law. The law must be clear and concrete so that it can be enforced.

(4) There should be an overall plan to control the mountains and streams together. In the remote mountains, the plan should mainly be afforestation and nurturing the sources of water. In the low mountains and hills, economic forests should be quickly developed to produce firewood and other usable timber. In matters of river and stream management, the principle of combining biological measures with engineering measures must be implemented. When dikes and dams are being constructed, protective forests should be planted so as to reap the maximum protective benefits. The work of water and soil conservation of the southern part of Shaanxi must be strengthened and a water conservancy organization must be established in order to carry out the work well.

(5) Scientific research should be strengthened to study the natural ecological system of these mountains and the effects of human activities on the ecological system, to study the structural characteristics, the function, and especially the load capacity of the forest system with respect to economic activities, and to study the reasonable way of managing the natural resources, their development, and utilization. These studies will provide a scientific basis for developing the natural resources of the Qinling Bashan region and to preserve its ecological balance.

DEVELOPMENT OF FAVORABLE CONDITIONS FOR PIG RAISING

Xian SHAANXI RIBAO in Chinese 21 Jan 82 p 2

[Article by Commentator: "Consolidate and Develop Favorable Conditions for Pig Raising"]

[Text] Since the Third Plenary Session of the 11th Party Central Committee, pig raising in our province has developed at a steady pace and the outlook is most favorable. Since 1979, there has been a large increase both in the number of pigs out of inventory as well as in the quantity of meat produced. There is enough pork not only to meet the needs of the province but also to supply other provinces. There are signs, however, that pig raising is in a downward trend, as the number of sows and pigs in stud is being sharply reduced. By the end of November 1981, the number of sows throughout the province had dropped by 350,000, while there were only 1 million pigs in stud. There was, on average, only 1 male pig for every 35 sows. Unless this problem is promptly dealt with, it is likely that the number of pigs will continue to decline and that a shortage of pork will occur. The governments at various levels must therefore keep a clear head and take prompt measures to consolidate and develop favorable conditions for pig raising.

While there are many factors accounting for the downward trend in pig raising, the main reason is the shortage of animal feed as a result of reduced autumn crop production. The "difficulty of selling pigs" has greatly damaged the positive attitude of the peasants for raising pigs. Another reason may be attributed to the fact that those in leadership positions at various levels failed to foresee the new situation which would arise with the implementation of the responsibility system in agricultural production and to exercise their leadership in pig raising in a vigorous manner. To reverse the downward trend and maintain this year's level at approximately that of last year, it is absolutely necessary that the various levels of government as well as the concerned departments should regard pig raising as a matter of major importance.

The primary requisite for the development of the pig-raising industry is to increase the number of pigs in stud as well as the number of sows in order to ensure the supply of pigs. Every area where 7 to 10 families do not have a sow for breeding purposes and where there is not an average of 1 male pig for every 25 sows must take positive steps to remedy the situation. Those areas where the number of sows is particularly small must "keep all sows in stock without being selective" in order to increase the number of pigs. State-operated food stations, livestock veterinary stations, and breeding stations which have the means to do so must take it upon themselves to breed male pigs. Pig-raising collectives must give priority to the raising of male pigs and sows and supply piglets to the commune members. At the same time, in meeting the new situation that is accompanying the implementation of the responsibility system in agricultural production, they must actively promote the raising of sows by commune members and offer them whatever assistance they may need. They must exercise strict control over the outflow of sows and place a ban on the indiscriminate slaughtering of pigs and the castrating of male pigs. Peddlers must not be allowed to engage in the selling of sows.

The policy on pig raising must be strictly enforced. The series of policies which have been adopted in the past must continue to be implemented and must not be allowed to lapse or to be altered. Those production teams with household production contracts but where the households do not have a collective stock of grain must raise a supply of grain according to the size of the cultivated land or the production contract quota so as to ensure the sale to the commune members of animal feed for pigs. The various areas must also adopt the method of awarding brisk-selling industrial products to the production teams and professional breeders or of allowing them to buy such products in order to encourage them to make an extra effort in the raising and selling of pigs. The production teams are to be responsible for purchasing to meet the purchasing quota set by the government. In implementing the responsibility system in agricultural production, the production teams must assign to units and families the job of breeding. The government's food departments and the production teams must sign contracts setting the purchase quotas and stipulating the responsibilities and benefits for both parties. Contract terms must be met. Any party that fails to fulfill the terms of the contract must be held responsible for the losses incurred. The purchasing departments in various areas must improve their style of doing business and the way they go about purchasing pigs. For the convenience of the masses, they may go to the sellers to make advance payments. At the present time, pigs held in stock by the masses must be purchased without delay. In the future, when pigs have reached the standard size for selling, food departments must not refuse to buy them or deliverately lower the grade of the pigs and the purchase price and thereby make things difficult for the masses. The "difficulty of selling pigs" must not be allowed to happen again. After the pig-raising production teams and the commune members have met the quota set by the government for the sale of pigs, they may be permitted to sell the surplus to the government, or they may be given a permit by the food stations to slaughter the pigs for their own use, to be shared or to be sold. The price, however, must not be raised. The small number of speculators must be sternly dealt with according to the law.

BRIEFS

GOVERNMENT SUPPORT--In order to reverse as soon as possible the downward trend in pig production and to ensure the supply of vegetables to the cities and mining areas, the provincial government has authorized the departments of finance and agriculture to allocate 1 million and 2 million yuan, respectively, to support the raising of stud pigs and sows and the production of vegetables. The provincial departments of finance and agriculture have recently made such funds available to the concerned regions and cities and have sent out notices requesting the production teams in the communes to continue to adhere strictly to the principle of primarily emphasizing self-reliance and counting on government support as a secondary measure, to ensure that the special funds are used for their designated purposes, to strive for the achievement of economic benefits, and to refrain from misappropriation and waste. ILLEGAL SUGAR PROFITEERING PUNISHED

Chengdu SICHUAN RIBAO in Chinese 30 Jan 82 p 1

[Article by Shen Wuzhong [3476 2976 1813]: "Resale of Sugar at High Price Brings Economic Punishment to Daxian Prefecture Units"]

[Text] Acting in coordination with municipal and county price units and industrial and commercial departments, the Daxian Prefecture Commodity Price Commission has meted out economic punishments to individual units that had resold sugar at high prices.

On two occasions in September 1981, the Zhaojia Amalgamated Industrial and Commercial Fruit Company in Daxian Prefecture bought 24,300 jin of sugar from Binlang Commune enterprises in Daxian at 0.80 to 0.81 yuan per jin and passed it along at the high price of 0.90 to 0.92 yuan to Daxian farms, Dazhu County commune and brigade enterprises, and to Bazhong County agricultural, industrial, and commercial units. It also sold some in Daxian markets at a retail price that was 0.24 yuan per jin higher than the national list price. After the Municipal Industrial and Commercial Bureau called a halt, it refused to change and sold another 1,500 jin of sugar. As a result of the aforementioned transactions, this company illegally gained a profit of 2,158 yuan. Acting in accordance with price policies, the prefecture and municipal commodity price commissions confiscated these illegal profits, and fined the company 700 yuan. Orders were also issued for the transfer at list price to beekeeping farms and horticultural farms in the prefecture for use in production 5,600 jin of sugar that had been frozen to offset state plan supply quotas.

The supply and marketing managing department for Weijia Commune enterprises in Dixian illegally bought 8,000 jin of sugar from outside the province, which it then sold at high prices and passed along to the Dixian commune and brigade enterprises supply and marketing company, deriving 609 yuan in illegal profits from the deals. The supply and marketing company, in turn, made wholesale sales to some retail outlets in Daxian Municipality, making a profit of 250 unit therefrom. The Prefecture Commodity Price Commission decided to confiscate the illegal profits in entirety, to fine the supply and marketing management department of Weijia Commune enterprises 300 yuan, and to fine the supply and marketing company of Dixian Commune and brigade enterprises 200 yuan.

SITUATION REPORT GIVEN ON THREE LIVESTOCK RAISING ZHOUS

Chengdu SICHUAN RIBAO in Chinese 28 Jan 82 p 1

[Article by Grasslands Department, Provincial Animal Husbandry Bureau: "Ganzi, Aba, and Liangshan Zhou Animal Husbandry Industry Production Situation Good. Various Forms of Responsibility Systems Established; Scientific Livestock Raising Practiced"]

[Text] Guided by the spirit of the 3rd Plenary Session of the 11th Party Central Committee, party and government units at all levels in Ganzi, Aba, and Liangshan Zhou continue to carry out the spirit of the Provincial CCP Committee Sanzhou Work Conference, to implement production programs, to establish production responsibility systems, and to practice scientific livestock raising for a fine situation in animal husbandry production. In 1981, livestock on inventory numbered 13,352,000, and livestock removed from inventory numbered 2,149,000, a 357,000 head increase over 1980, for a meat output of 129,070,000 jin, which was an increase of 65.75 million jin. Large livestock animals, sheep and goats raised by herdsmen or peasant commune member households numbered 3.27 million, a 19 percent increase over 1980.

Production accounting units in more than 90 percent of the rural communes and production brigades in these three zhou have established various forms of animal husbandry responsibility systems linked to output. In pastoral areas, mostly responsibility systems of specialized contracting, fixing output quotas based on groups, on individual workers, or on households have been established under uniform management, with "five fixeds and one reward", calculation of compensation linked to output. In semi-farming semi-pastoral areas, responsibility systems of "double contracting" and linking output to groups have been instituted. In addition, responsibility systems linked to output have been combined with technical promotion responsibility systems and cadre personal responsibility systems, which has helped implementation of various production measures and the promotion of science and technology, not only promoting livestock industry production, but also enhancing the building of the grasslands. Building of man-made grasslands amount to 77,000 mu; improved grasslands amount to 258,000 mu; and establishment of fine variety pasture grass bases amounts to more than 10,000 mu. Rodents and insects have been exterminated on more than 2 million mu. In 1981 operation of integrated herding, industrial, and commercial businesses increased. In 1981, the

Ruoergai Integrated Herding, Industrial, and Commercial Enterprise made profits of 2.81 million yuan for an average increase of 22.3 yuan per capita of the population engaged in agriculture and livestock raising. Hongyuan County's operations had 1.3 million yuan profits from sales in excess of plan from livestock product processing. Cadres and commune members said, "Taking the path of integrated herding, industrial, and commercial business benefits the state, the collective, and individuals, and is the path by which nationality areas cure poverty and become wealthy." In addition, Key livestock raising households and specialized households have begun to develop. Ma Yongming [7456 3057 2494], commune member from Waibei Commune in Huili County raised 80 sheep, seven large livestock, eight hogs, and 14 hives of bees for earnings in 1981 of about 4,000 yuan.

At the present time, the three zhous are in process of further implementing various party programs and policies for semi-agricultural semi-pastoral areas, and doing a solid job in the overwintering of livestock into spring to hasten development of the livestock industry.

READJUSTMENT OF CROP PATTERNS, DIVERSIFICATION CREDITED FOR GREATER OUTPUT

Chengdu SICHUAN RIBAO in Chinese 29 Jan 82 p 1

[Article by Correspondent Ceng Xudong [2582 2385 2639]: "All-around Bumper Harvest for Liangshan Zhou Last Year. Equitable Readjustment of Internal Structure of Agriculture and Crop Patterns"]

[Text] Liangshan Yi Nationality Autonomous Zhou equitably readjusted the international structure of its agriculture and its crop patterns to win an all-around bumper harvest in agriculture during 1981. Throughout the zhou grain output increased and economic diversification developed fairly rapidly, output of staples such as sugarcane, tobacco, rape seed, silkworm cocoons, livestock and aquatic products increasing by from 2.9 to 39.3 percent.

In Liangshan Zhou, which is inhabited by more than 20 different nationalities, among them the Yi and the Han, though the mountains are huge, ravines deep, and climate complex, there are semi-tropical low hills and river valleys that produce mostly paddy rice and sugarcane. There are vast medium size mountain and semi-mountainous areas that produce prolific amounts of rice, wheat, and tobacco. There are vast tracts of frigid and temperate zone high semi-mountainous regions where water plants abound, and where grain as well as forestry and the livestock industry can be developed. There are frigid zone high mountain regions with dense forests and broad grasslands, and there are more than 340,000 mu of freshwater water surfaces. In 1981, all levels of party and government units throughout the zhou vigorously implemented a production program of "taking forestry and livestock raising as the key link in a combination of farming, forestry, and livestock raising for all-around development of economic diversification." They steadily carried out a readjustment of the internal structure of agriculture and crop patterns, and proceeded from realities to make suitable reductions in the areas sown to wheat, rice, and potatoes, using it for expansion of the growing of economic crops such as rape, sugarcane, tobacco, soybeans, and hot peppers, and for the reversion of cultivated land to forests and pasturage. They farmed scientifically, and not only did grain yields per unit of area rise tremendously, but total output also exceeded that of the preceding year. Moreover, income from economic diversification into forestry, livestock raising, sideline occupations, and fisheries increased 31.3 percent over the previous year.

INCREASED DIVERSIFICATION IN AGRICULTURE REPORTED

Chengdu SICHUAN RIBAO in Chinese 29 Jan 82 p 1

[Article: "More and Faster Economic Diversification in Neijiang Prefecture. Collectives and Individuals Rise Together. 'Watermelons' and 'Sesame' Require Attention"]

[Text] In the course of leading economic diversification, party and government units at all levels in Neijiang Prefecture have diligently implemented party policies and have brought into full play the enthusiasm of both collectives and individual commune members to bring about a tremendous increase in output value from economic diversification. Despite the especially great flood disasters of 1981, the prefecture's total grain output still increased slightly over the previous year. Cotton, oil-bearing crops, and jute output increased tremendously, and most items in the planting and breeding industries overfulfilled plan. Statistics from the Prefecture Statistical Bureau show gross output value from economic diversification in the prefecture to have been about 680 million yuan, a 15 percent over the previous year. Average per capita income may reach 94 yuan, a net increase of 12 yuan over the previous year.

Neijiang Prefecture located in the Tuo Jiang basin has extremely superior conditions for development of economic diversification. As a result of readjustment of the internal structure of its agriculture and its crop patterns since the Third Plenary Session of the 11th Party Central Committee, substantial development has occurred in its economic diversification. But the collective has moved ahead rapidly while development of commune member household sideline occupations has been slow. Following investigation and study last spring, the Prefecture CCP Committee and government administrative offices put forward ideas and actions to be taken for vigorous development of economic diversification, requiring the bringing into full play of the enthusiasm of collectives and individuals, with the organization under unified production team and production brigade leadership of various kinds of specialized teams, and specialized groups, and the designation of specialized households and specialized workers for teh signing of contracts. The prefecture further promoted the "four specializations and one contract" responsibility system linking calculation of compensation to output. It encouraged voluntary combination in production teams practicing large scale assignment of responsibilities for joint operations among households. All projects that lend themselves to performance by individual commune members, commune members should be allowed to perform to the maximum possible extent, production teams helping out with organization or providing support. A policy of adptation of general methods to local situations, broadening avenues, making the most of advantages, and accentuating strengths while avoiding weaknesses was emphasized. While maintaining ecological balance, attention was given to what grows in the ground, flys in the air, swims in water, and is raised at home. Equitable provisions were made for planting, breeding, collecting, and processing.

With the implementation of policies, enthusiasm of cadres and the masses made an upsurge, and the path for practicing economic diversification was wider and methods greater. In 1981, in addition to giving attention to staple economic crops and key economic diversification projects, the prefecture's farflung cadres and masses devoted serious attention as well to traditional non-staple economic crops and sideline occupations, achieving both the holding of "watermelons" and the picking up "sesame seeds" at the same time, and obtaining economic benefits from "seeking wealth in every quarter, and having treasure come in from everywhere." The prefecture's economic crops of cotton, rape, peanuts, jute, hot peppers, ginger, watermelons, mushrooms, and citrus fruit, as well as forestry, and hogs, sheep and goats, rabbits, chickens, ducks, and geese all increased over 1980. Cotton increased 15.8 percent; rape increased 28.9 percent; peanuts increased 20 percent; jute increased 23.6 percent, ginger increased 3.4 fold; and watermelons increased 1.3 fold. Very great development also occurred in commune member household sideline occupations. On the basis of investigations conducted among 366 commune member households in eight counties and one municipality in the prefecture, the Prefecture Statistical Bureau reported that last year commune member household sideline occupation earnings increased by between about 20 and 30 percent over the previous year.

TITLE: "Nowcasting of Disastrous Severe Storms and Joint Preparations"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 2, 10 Feb 82 pp2-4

ABSTRACT: Currently, the extremely important problem in weather forecasting is the sudden development of very damaging storms, which are often accompanied by violent wind, heavy rain, hail, thunder, tornado, and even mountain torrents. Although more have been learned about such swift change of weather, to predict it remains a difficult problem. For the purpose of providing some warning, the work of nowcasting has been given considerable attention in foreign countries, such as the USA, Japan, England, Canada, etc. In Aug 81, the world meteorological organization held a conference in Hamburg to discuss the science of nowcasting. Some Japanese and US specialists claim that this is the direction of service of weather forecasting in the 80's. Following a brief introduction of the condition of nowcasting reach and practice in foreign countries, similar work in China, primarily in Hunan, Anhui, Jilin Railway system, and some urban weather stations are briefly described. Such nowcasting experiments are being carried out in the 4 years of 1977-80 and have become a very popular program. The rate of accuracy for predicting rains may reach 84 percent and the duration of prediction before the event is 62 minutes on the average.

TITLE: "Climatological Features of the Dry Wind in the Hexi Corridor Region of Gansu Province"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 2, 10 Feb 82 pp 23-25

ABSTRACT: The dry wind is one of the major damaging meteorological phenomena affecting high and stable yield of wheat in the Hexi Corridor. It usually occurs in the first part of Jun to the early to middle part of Jul, during the blooming-milk ripe stage of wheat. It can cause various degrees of damage to more than 2/3 of the 4 million mu of wheat in these 15 counties. The yield reduction may reach 10-20 percent. Based upon observational and experimental data of the past several years and related survey reports, this paper analyzes the meteorological characteristics of this dry wind and attempts to classify it. Preventive measures, including afforestation to stabilize the sand, protect the cropland, and improve the microclimate of the fields, sprinkling ash-water on wheat plants, lightly irrigating wheat fields 1-2 days before the dry wind, and mixing seeds with such chemicals as cycocel, calcium chloride, etc. in solutions before planting are proposed.

ORG: Jiaxing Prefecture Weather Station, Zhejiang Province

TITLE: "Long Term Forecasting of Scab Fungus Disease of Wheat"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 2, 10 Feb 82 p 25

ABSTRACT: In recent years, the author and colleagues analyzed and compared weather data with information concerning the condition of the scab disease of wheat to formulate a system of forecasting this disease. The analysis and study disclose that the extent of this disease has a close relationship with the average temperature of September of the previous year and the rainfall of the winter, from Dec to Feb. The experimental equation of $J_1 = T + KR$ is obtained: where T is the average temperature of Sep; K is an experience coefficient = -0.0437; R is the winter rainfall. Through computation, the following indices are produced: (1) If $T \geq 24^\circ C$, it is a mild year for scab; (2) If $J_1 < 15.35$, it is a severe year for scab; (3) If $J_1 > 15.35$, it is a mild year for scab. These 3 indices have been used to check the condition of scab for several recent years to prove them to be basically accurate as a technique for predicting the condition of scab.

I. GENERAL INFORMATION

BRIEFS

NORTH CHINA RAINFALL--Beijing, 13 May (XINHUA)--Northern China's winter wheat growing areas experienced rainfall from 10 to 13 May. Precipitation ranging from 10 to 40 millimeters was recorded in drought-stricken Shanxi, Hebei, Henan, western Shandong, northern Jiangsu and Anhui and in the southern part of Central Nei Monggol. Precipitation of more than 40 millimeters was recorded in Xing and Yuanping counties in Shanxi, Shenxian County in Shandong, and Xiaxian and Luanchuan counties in Henan. According to the Central Meteorological Station, the rainfall has alleviated the dry spell in the aforementioned areas and benefited winter wheat and spring crops. Rainfall in southern Shandong, southern Shanxi and southern Liaoning was generally less than 10 millimeters. [Text] [Beijing XINHUA Domestic Service in Chinese 0729 GMT 13 May 82 OW]

BRIEFS

MINQIN COUNTY HOGS--Lanzhou, 16 May (XINHUA)--Over the past 3 years Minqin County, Gansu, has increased the number of hogs in stock by more than 10,000 head a year. Last year the county raised over 130,000 hogs, an alltime high. [OW141131 Beijing XINHUA Domestic Service in Chinese 0052 GMT 10 May 82 OW]

COLD WEATHER FORECAST--A cold air mass has moved into the Hexi corridor, Gansu Province, from North Siberia in the Soviet Union. It is forecast that the weather in Gansu Province will become cloudy 11 and 12 May. Most areas will have light or medium rainfall and snowfall. Gannan Tibetan Autonomous Prefecture will have a heavy snowstorm. The temperatures in the North Dingxi Prefecture and in the east part of the province will drop 8 to 11 degrees. Those in other areas will drop 6 to 8 degrees. After the cold rainy days, the Hexi mountainous areas will be hit by severe frost on the mornings of 12 and 13 May. The east part of the province and the North Dingxi Prefecture will be stricken by frost on the mornings of 13 and 14 May. Except for southern areas of the province, other areas throughout the province will be affected by frost. [SK120919 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 11 May 82 SK]

METHODS TO SMOOTH FLUCTUATIONS IN LATE CROP NOTED

Guangzhou NANFANG RIBAO in Chinese 17 Mar 82 p 2

[Article: "How Can Great Fluctuations in the Late Crop Be Changed? Some Agricultural Specialists in the Province Have Made a Scientific Analysis of Reasons for Decreased Yields in the Late Crop During Any Given Year, and Feel that the Guiding Mentality Should Be to Establish Consistency and Then Work from Consistency for Increases"]

> [Text] Editor's Note: People may possibly ask, since now is the time for doing a good job of spring farming, why in the world should anyone seek out agricultural specialists and persons in charge in agricultural units to concentrate on the study of problems in late crop production? People who truly understand agriculture will realize that only through early study of this important problem can locking the barn after the horse has been stolen be avoided; only in this way can there be no missing out on the farming season, and only in this way can one talk of fighting a battle for which one is prepared. In another two months, it will be time to sow the late crop, and if specialists are asked then, it will be too late to do anything with their advice.
>
> Large fluctuations in late crop yields are a repetitious phenomenon in Guangdong Province's grain production. How to carry forward the achievements of "large upswings" in the late crop, and especially how to avoid a passive situation of "large downturns" is a crucial issue for late crop production. An historical analysis of this issue by agricultural specialists has provided some views that accord with science rather well, and this is a contribution to development of the province's agriculture. While they are doing a good job of spring farming, this will greatly help every jurisdiction do a good job of late crop production with more initiative and more foresight than in former years.

While doing a good job of current spring farming and production, how can preparatory work for the late crop be done early in order to change a situation of "large ups and downs" in late crop production? Recently the Provincial CCP Committee assembled in Guangzhou a group of agricultural specialists, scientific and technical personnel, and persons in charge of agriculture in each of the province's prefectures to discuss this problem. The chairman of the Standing Committee of the Provincial CCP Committee and concurrent director of the Provincial Agricultural Committee, Du Ruizhi [2629 3843 5347], gave a speech at the meeting. After seven days of repeated explorations, comrades attending the meeting came to the conclusion that the guiding mentality for late crop production should be "to establish consistency and then work from consistency for increases." Specific measures would require "accentuating advantages and avoiding disadvantages, with a combination of avoidance and resistance."

Since entering the 1970's, late crop production in Guangdong Province has been very inconsistent. During the period from 1970 to 1981, 7 of the 12 crops had reduced yields, the degree of decrease sometimes being very great. For example, in 1975 late crop output for the province as a whole totaled 14.4 billion jin, declining in 1976 to 12.9 billion jin, a drop in output of 1.5 billion jin. In 1977, total output from the late crop again rose to 16.38 billion jin only to fall again in 1978 to 13.79 billion jin, a drop of 2.5 billion jin. A comparison of 1981 with 1980 also showed a drop of about 2 billion jin.

Formerly, in analyzing reasons for reduced output from the late crop, quite a few comrades took into consideration only abnormal changes in the weather. At this meeting, many comrades acknowledged that weather abnormalities had a very great influence on late crop output; however, if work is done well in every aspect, small disasters can be made to result in no decrease in output, and large disasters can be made to result in only small reductions in output. Comrades from Zhaoqing Prefecture made a concrete analysis of a drop in output totaling 1.16 billion jin in the years 1976, 1978, 1979 and 1981 in a search for contributory factors of many different kinds. First was an estimated loss of about 480 million jin of output attributable to unfavorable weather about which little could be done. This amounted to 41.4 percent of the total drop in output. Second was damage resulting in a drop in output caused by insufficient coordination of technical measures, such as insufficiency of organic fertilizer, improper fertilization, and retrogression in seedling propagation techniques. This caused a drop of about 400 million jin or 34.5 percent of the total drop in output. Third was late sowing and late transplanting; weak seedlings with poor resistance, small heads of grain with a small number of grains per head, producing a drop in yields. In 1981 when the late crop was transplanted latest, the drop in output amounted to about 280 million jin, or 24.1 percent of the total drop in output. Plant protection specialist Wu Shangzhong [0124 1424 1813] noted that natural conditions for the late crop were fairly severe in 1981, and that in addition to damage caused by typhoons, flooding and cold, damage from diseases and insect pests was also conspicuous. Statistics show an area of more than 100 million mu (times) in the province stricken with rice diseases and insect pests, and losses to paddy resulting from blast, bacterial blight and sheath and culm blight are estimated to have amounted to 650 million jin. From this it may be seen that drops in late crop output cannot be attributed entirely to natural disasters, and that one cannot regard only wind and water as disasters.

After the specialists had made a comprehensive analysis of reasons for drops in the late crop, they made a point of saying that a good job of late crop production required a guiding mentality of "establishing consistency and then working from consistency for increases." The major contradiction in late crop production at the present time is lack of consistency, and this is particularly the case in central grain producing regions. The central region grows about 20 million mu of paddy rice, and if output there could be made consistent, it would be possible to build from consistency toward high output. The area plays a decisive role in winning a bumper grain harvest for the province as a whole. On the basis of weather conditions, the specialists set the safe heading periods for late crop paddy rice, dividing the entire province into three zones as follows: the North Guangdong Mountain Zone, being the northern mountain zone from the mouth of the Lian Jiang in Yingde west to Guangning, and Huaiji, and east to Fogang, Xinfeng, Heping and Xingmei, where the "cold dew wind" arrives early and where opportunities are small for a rise in temperatures for the late crop thereafter. Here mostly "avoidance" methods should be used, meaning that heading of the late rice crop should take place before the arrival of the "cold dew wind." The Qiong-Lei Zone, including the Leizhou Peninsula and Hainan Island, where the main danger is from typhoons and torrential rains, waterlogging and water stagnation, requiring "resistance" as the main method to be used in a combination of "resistance" and "avoidance." Varieties with strong resistance should be selected. The central zone, including Shantou, Huiyang, Foshan, Zhaoqing, Meixian and a part of Guangzhou, which is affected by both typhoons and torrential rains and the cold dew wind, as well as low temperature cold damage. Measures required are "avoidance" principally in a combination of "avoidance" and "resistance." This means that arrangements should be made so that the heading period for rice comes around 10 October, and so that the period of full heading of sitting autumn varieties is before 1 October. In addition, varieties with strong resistance should be selected, and scientific farming and management should be intensified.

In order to achieve the goals of "avoidance" and "resistance," comrades attending the meeting believed that it is necessary, first of all, to achieve an equitable crop pattern for various varieties, i.e., a suitable matching of early, intermediate and late ripening varieties with no growing of a single variety over a wide area, and particularly avoiding the growing of a late ripening variety over a wide area. Otherwise, avoidance of disastrous weather would be difficult. Next, everything has to be done in its proper order to achieve properly early sowing and transplanting. Third, healthy body growing methods must be used, propagating sturdy seedlings and fertilizing adequately with base fertilizer to lay a good foundation for increasing seedling resistance.

In order to implement measures for consistently high yields from the late crop, the Provincial Agricultural Committee required all prefectures to act in accordance with new circumstances in rural villages to strengthen leadership of agricultural production, to improve methods for serving agriculture, and to restructure agriculture technical service organizations for genuine achievement of reliance on policies and science to win bumper harvests from the late crop.

BRIEFS

SUGAR FARMING TECHNOLOGY--Work has begun in China's Guangdong Province on a 500-hectare project to introduce Australian sugar farming technology to China. The project, resulting from cooperation between Australian trade officials and private consultants, is regarded by the Chinese Government as an important step toward mechanization and efficiency in China's growing sugar industry. Radio Australia's Beijing correspondent Richard Thwaites says it is worth close to a million dollars in form of equipment by Australian companies. Last year, China bought around 100,000 tons of sugar from Australia. [Text] [Melbourne Overseas Service in English 1230 GMT 3 Apr 82]

BRIEFS

AUSTRALIAN EXPERTS SERVICES--A team of Australian experts is leaving for southeast China next month to act as long-term advisers on a forestry project. The project, near Nanning in the Guangxi Zhuang Autonomous region, aims to provide training in low-cost methods of increasing forestry production. It is one of two projects that have already begun under the technical cooperation for development agreement signed last October by China and Australia. The other project underway is in Beijing where seven Australian advisers are helping to improve teaching methods in the English language at a foreign language institute. The long-term aim of this project is to enhance the English language skills of Chinese technical personnel who have to study abroad in English. So far, China has requested Australian assistance in about 40 projects under the technical cooperation agreement. Most of the projects would be in agriculture, such as soil conservation, pesticide control and beef and dairy production, but feasibility studies are being undertaken on a wide range of other projects, including some in the health field, in civil aviation, in petroleum exploration and in (?auditing). POLICIES ON COMMUNE-BRIGADE RUN ENTERPRISES ANALYZED

Shijiazhuang HEBEI RIBAO in Chinese 24 Mar 82 p 2

[Article by Political Study Department, Provincial Commune and Brigade Enterprises Bureau: "Questions and Answers About Several Commune and Brigade Enterprise Policies"]

[Text] Question: What is the present program for development of commune and brigade enterprises?

Answer: Commune and brigade enterprises must adhere to a socialist orientation, actively produce products needed by society, principally serve agricultural production and the people's livelihood, but also serve large industry and exports. Development of commune and brigade enterprises requires adaptation of general methods to local situations in accordance with availability of local resources and social needs. There should be no attempts to "make bricks without straw," no operation of processing industries with excess production capacity, no competition for raw materials and power with large industrial enterprises, and no destruction of national resources. They may also actively experimentally operate integrated agricultural, industrial, and commercial enterprises.

Question: What is the scope of commune and brigade enterprise operations?

Answer: The scope is very broad and the variety of matters numerous. A few major ones are provided here for reference. There is farming and breeding of aquatic products; agricultural products processing industries; industries making things for use in agriculture such as manufacture of small farm machines and implements and the repair and renovation of farm machines; fuel, and processed and raw materials industries and power industries, the operation of hydroelectric power stations and pit head thermal power stations below 12,000 kilowatts being permitted. They are allowed to undertake, on behalf of large industries, production of diffuse spare parts and of some products. Depending on needs and capabilities, they organize construction teams, and transportation, loading and unloading teams to undertake city and countryside capital construction, hauling, loading and unloading tasks. Where resources and skills permit, they may produce traditional handicrafts and export items. If local requirements exist, they may operate businesses or service trades such as tailoring, repairs, lodging houses, food supply, or trade warehouses.

Question: What consideration does the country show commune and brigade enterprises in tax collection matters today?

Answer: In order to foster development of commune and brigade enterprises, the state practices a policy of low taxes and exemption from taxes. Specific provisions are as follows: Products produced by commune and brigade enterprises for direct use in agriculture, as well as vocational earnings from items that commune and brigade enterprises make to serve the livelihood of their own commune members, may be carried on the books as specific items and services, and are thus exempt from collection of industrial and commercial taxes. Except for the production of items taxed at a high rate such as tobacco, spirits, sugar, cotton yarn, and wristwatches, on which industrial and commercial taxes are levied in accordance with regulations, income from the production of other goods and from vocations, as well as sugar produced by places in which processing capacity is inadequate and for which taxation in accordance with regulations would work hardships, are given reduction or exemption from industrial and commercial taxes for periods of less than a year. The point at which taxes begin to be levied on commune and brigade enterprises has been changed from the former 600 yuan of income for the entire year to 3,000 yuan, the tax rate being 20 percent. All earnings below the tax levy point are exempt from taxation. Except for enterprises that compete for raw materials with large advanced industrial enterprises and enjoy considerable profits, which are taxed as income according to regulations, depending on indivudual circumstances, other newly opened enterprises are given a 1 to 2 year exemption from taxes. (In cases where following the period of tax exemption payment of taxes would work hardship for specific enterprises, another year's exemption from taxes may be granted.) Profits derived from production of items that serve agriculture directly such as chemical fertilizers, pesticides, veterinary medicines, and the manufacture of farm machinery and implements, and profits that derive from enterprises that directly serve commune members' livelihoods such as beancurd workshops, flour mills, soy sauce workshops, processing of grain and cotton, barbershops and tailor shops may, if special consideration is genuinely needed, be listed as products and services and, following approval by the Provincial People's Government, may be exempted from income taxes. Commune and brigade enterprises in border region counties and national minority autonomous counties (or banners) shall continue to be exempt from payment of income taxes from 1979 until 1983. Disaster area communes and brigades engaged in production of relief items may receive special consideration for a fixed period of time for reduction or exemption of industrial and commercial taxes, and income taxes. Commune and brigade enterprises are to strictly carry out revenue collection policies, no cheating on taxes, evasion of taxes, or late payment of taxes due permitted.

Question: How should commune and brigade enterprise profits be distributed and used?

Answer: The welfare of the country, the collective and individuals must be taken into consideration. First, taxes must be paid and loans that are due repaid. Withholdings for the enterprise are to be assured in order to expand reproduction. Distributions of returns to brigades are to be assured to raise commune members' standard of living. Depending on earnings from agriculture, industry, and sideline occupations, equitable arrangements should be made for capital construction investment and collective accumulations. On the basis of the foregoing principles, it is necessary to proceed from realities, to adapt general methods to specific places and specific enterprises, and through mass discussion to democratically determine the proportions to be withheld for enterprise expansion of reproduction, for payment to communes and production brigades as public accumulation funds and public welfare funds, and for distribution to production team commune members.

Use of enterprise profits remaining has to proceed from realities in the enterprise, democratic discussions being held to decide proportions for augmentation of circulating capital, use in increasing fixed assets, technological innovation, improvement of equipment, use for public welfare and for welfare services. Use of public welfare and public accumulation funds tendered to communes and production brigades also has to be decided by discussion of commune member representative assemblies, specific purposes being agreed upon. No individual leaders may arbitrarily approve use of commune and brigade enterprise profits; they may not squander or waste them; and they may not use them to invite people to dine or to provide gifts. Such unhealthy tendencies are to be resolutely corrected.

Question: What forms of responsibility systems should commune and brigade enterprises promote now?

Answer: Hebei Province's commune and brigade enterprises are spread out over a wide area, and their conditions vary. They should adapt general methods to local situations and to local enterprises in formulating production responsibility systems. The following several forms are fairly universal at the present time:

First is commune and brigade responsibility systems instituted in enterprises. Their main forms are as follows: Assumption of sole responsibility for profits. All that complete profit plans on time are provided equitable remuneration with no bonuses and no penalties. Overfulfillment of profit plans and unfulfillment of profit plans is proportionately rewarded or penalized. Distributions of profits is done on the basis of profits earned, a suitable proportional distribution being set, the more earned the greater the distribution; the less earned the smaller the distribution. Large-scale sole assumption of responsibility is practiced, the amount of profits to be paid to higher authority set and all profits in excess of that amount reverting to enterprises for their disposition, communes and brigades not being further involved.

Second is responsibility systems within enterprises for workshops, groups (or teams), and individuals. Their most common forms are: Overfulfillment of piece rate wages: Equitable calculation of production norms for each employee on the basis of different kinds of work done, a standard wage being paid for fulfillment of norms, additional wages to be paid in cash for overfulfillment of norms on the basis of quantity, quality, and consumption criteria. For failure to fulfill norms, a docking of wages figured on the basis of conversion to monetary terms of shortfalls in product output. For both group and team accounting and assumption of sole responsibility for profits, the enterprise fixes on workshops, groups and teams the various output value, profit, and production expense criteria, and when they are overfulfilled, a certain amount of the overfulfilled portion is withheld for bonuses. The form of responsibility system of independent accounting, responsibility being placed on individuals, is the same as the method of assumption of sole responsibility in the figuring of profits. It is generally used for independent work such as for chauffeuring, electrical work, maintenance work, and service industries. Floating wages: One kind of floating wage provides payment of a basic wage plus a wage that fluctuates up and down depending on how well the enterprise produces. Another kind provides for no basic wage, but rather a certain proportion is withheld from gross profits as wages for workers, distributions made in accordance with task fulfillment by individual workers. In sole responsibility for profits, all overfulfillment goes to the person bearing the responsibility. The enterprise enters into a contract with individuals, which sets the amount of sums to be paid the collective, all excess to go to the individual, commune members being individually responsible. Unified management with dispersed processing and withholding of profits: In this method, the enterprise assigns uniform production tasks to commune members within the enterprise, and also provides them with the same raw materials, carries out uniform inspection of goods quality prior to acceptance, and conducts centralized marketing and final settlement of accounts. From profits derived, a proper management fee is withheld, the remainder going to commune members individually.

Question: What principal policy regulations should the state have for commune and brigade enterprises engaged in processing of agricultural products?

Answer: All farm products that lend themselves to rural processing in accordance with rational economic principles should gradually come to be processed by commune and brigade enterprises. The setting of equitable base procurement figures for agricultural products can be done through contracts, all in excess of these base figures to be disposed of by communes and brigades as they see fit. This will provide commune and brigade enterprises with a realiable source of raw material for processing while, at the same time, commune and brigade enterprises can do processing for the state.

Question: What regulations are there about integrated commune and brigade enterprises?

Answer: The organization of integrated enterprises must certainly proceed from development of production, maintain the principle of voluntary participation, combine the lower and upper levels, proceed from the easy to the difficult, gradually develop participation in integrated operations, and not be limited to individual trades or industries region, or system of ownership. However, one cannot arbitrarily change the subordinate relations in the system of ownership of all parties to the integration, nor the debtor or creditor relationships with banks. If changes are necessary approval of financial or banking units has to be obtained. Also necessary is equality and mutual benefit with consideration of the economic benefits of all parties. Agreements or contracts should be signed that set the proportional sharing of economic results on the basis of what each party has provided including funds, raw materials, skills, workforces, worksites, equipment, and facilities. Diverse forms of integrated operations should be permitted with no rigid insistence on certain forms. So long as fulfillment of plan tasks handed down by the state are assured by the various forms of integrated enterprises, some of the products in overfulfillment of plan and products produced from raw materials that the enterprises have assembled themselves may be purchased by business or materials departments, and some may be disposed of as the enterprise sees fit in accordance with state policies, one enterprise supplying the needs of another.

Integration of raw materials producing areas and processing areas is to be promoted. Planned allocation quotas for raw and processed materials handed down by the state must be fulfilled first. Supply of raw materials for production to be used within integrated enterprises need not go through the intermediary links of business, supply and marketing, and materials, but direct allocation for supply may be practiced. Distribution of raw materials by the state is still done on the basis of the subordinate relationship between two parties, some being supplied directly, and some being organized for supply on site or nearby by commercial, supply and marketing, or materials departments. Commune and production brigade enterprises can also gradually try operating in conjunction with production teams and commune member households integratedly operated vicilian run enterprises, dividing up economic fruits. Wages and welfare benefits for all employees must be paid in accordance with original stipulations, and changes are not to be made lightly.

Once integration has taken place, unless discussion and agreement takes place about the original cooperative relationship among all parties, no ony may take it upon himself to break it. So long as conditions of the cooperative agreement are carried out, relationships with other enterprises outside the integrated unit may be conducted. Enterprises within integrated bodies organized on the basis of specialized cooperation may not "eat out of a large common pot." They must practice independent accounting.

FISH FARMING--Heilongjiang Province plans to invest 6 million to help communes and brigades develop fish farming. [Words indistinct] farming in the province. By the end of 1981, there were 2,400 fish-farming units run by communes and brigades in 69 municipalities and counties. Water areas for fish-farming totaled 1.64 million mu. The province plans to expand water areas for fish-farming to 2.25 million mu this year. [SK060633 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 4 May 82 SK]

AFFORESTATION PROJECTS--Heilongjiang Province overfulfilled its annual afforestation and sapling cultivation plan this spring. As of 11 May, the province had afforested 4 million mu of timber, fuel, economic and shelter forests, overfulfilling the plan by 14.3 percent, and cultivating 650,000 mu of saplings, overfulfilling the plan by 9 percent. Aside from this, 48 million trees and 17 million saplings had been planted and grown voluntarily by the people in the province. In the first year of the all-people afforestation campaign, as many as 9.6 million people have participated in afforestation activities--doubling last year's figure. [SK131220 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 12 May 82 SK]

PADDY FIELDS--Following the expansion of paddy rice fields in the past 3 years, Heilongjiang Province expands again paddy rice fields by 380,000 mu this year, bringing total paddy rice acreage to 4.99 million mu. There are over 10,000 mu of paddy rice fields in each of Suihua, Qingan, Nehe, Tailai, Gannan, Mulan, Huachuan, Tangyuan, Mishan, Hailin and Jidong counties. [SK070522 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 6 May 82 SK]

SOWING OPERATIONS--Bayan County, Heilongjiang Province, one of the marketable grain bases in the province, has made great progress in field crop sowing this spring. According to statistics, as of 7 May the county had sowed over 2.1 million mu of field crops and prefulfilled its field crop sowing plan by 4 days. The county's sowed acreage with improved varieties of grains this year accounts for 95.3 percent of the acreage of soybean and grains, surpassing the 1981 figure by about 20 percent. [SK120700 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 10 May 82 SK]

STRONG GALES--A gale which was as strong as grade 12 with a speed of 34 meters per second hit Shuangyashan on 11 May. This was the strongest gale ever recorded in the city. This strong gale destroyed some houses and 200,000 square meters of plastic sheet coverings for spring vegetables. The Shuangyashan Municipal CCP Committee and government are taking actions to combat disasters and send relief to the disaster area. [SK120827 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 11 May 82 SK]

WATER CONSERVANCY PROJECT--Subsidiary projects to harness (Anbanghe), (Yangyuanhe) and (Jielahonghe) rivers in Sanjiang plain, Heilongjiang Province, are under construction with state investment. Owing to narrow river courses and poor water-draining capacity, the 7.4 million mu of farmlands along these three rivers are often flooded. Though the main courses of these rivers were dredged a few years ago, water accumulating on farmlands cannot be drained due to the poor subsidiary irrigation systems. Construction of these subsidiary projects will be completed in 3 to 5 years. Over 5.5 million mu of farmlands will be aided. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 11 May 82 SK]

GOALS FOR BREEDING COTTON FOR JINGZHOU PREFECTURE DISCUSSED

Huanggang HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 1, Jan 82 pp 9-11

[Article by Fu Hengqian [0265 1854 6197] of the Jingzhou Prefecture Agricultural Zoning Office: "Several Viewpoints on the Cotton Breeding Goals in the Jianghan Plain"]

[Text] The Jianghan Plain is one of our nation's major cotton producing regions. The natural conditions are superior. Take Jiangling County as an example; the frostless period is as long as 270 days. The first day of frost for an 80 percent guaranteed rate of yield is 16 November. The last day of frost is 21 March. This provides a great productive potential for cotton which has an unlimited growth characteristic. To develop the superiority of the climate, and to develop the advantages and avoid the shortcomings, we should plant crop varieties that can fully utilize the effective light and heat resources of the locality and those varieties that have a strong adaptability to the unfavorable factors, so that the predetermined goal of "spending less money to realize large gains" can be realized. Some views on the cotton breeding goals for the Jianghan Plain are proposed here for discussion.

1. Reserve Strength of Intermediate Maturing Varieties

The cotton breeding goals for the Jianghan Plain generally emphasize early maturity and a clustered plant type suitable for dense planting and for the development of agricultural mechanization. It has always been believed that the Delta Pine cotton No 15 has a slightly late maturation time, therefore a lot of effort has been directed toward early maturity, while the selective breeding of intermediate maturing cotton varieties with reserve strength has been neglected. According to meteorological statistics of 27 years from 1954 to 1980 compiled at the Jingzhou Prefecture Meteorological Station (Jiangling), the average temperature of each 10-day period in September is always above 20°C. This is very beneficial to the growth and development of cotton fibers. The average temperatures of each 10-day period in October are all above 15°C. This is higher than the lowest temperature of 15°C required for the growth and development of fibers. Although this is not sufficiently ideal, it is enough for the fibers to develop fully. The average number of rainy days in September is 8.7. The amount of rainfall is 85.3 millimeters. The average number of rainy days in October is 9.3. The amount of rainfall is 76.4 millimeters.

This means, the weather in September and October consists mainly of sunny days. The temperature is high, sunlight is sufficient, and there is some rainfall. These are favorable to the formation and thickening of cotton fibers. Therefore, under the prerequisite of striving for more summer bolls, the Jianghan Plain has a superior climatic condition to produce several more effective autumn bolls. Cotton breeders should not neglect this climatic condition when selectively breeding new cotton varieties.

The flowering and budding periods of cotton in the Jianghan Plain frequently encounter plum rains. The boll forming period frequently encounters torrential rains, drought, waterlogging and attacks by diseases and insect pests. In addition, the measures of cultivation are sometimes inappropriate, which frequently causes massive shedding of cotton buds and bolls during the early period. If the reserve strength of a cotton variety is poor, its unlimited growth potential will be limited, and there will not be much hope for producing several more autumn bolls and the yield will not increase.

In the past, some people believed that cotton varieties with a strong reserve strength matured late. This insinuates a derogatory meaning, and is not appropriate. The concept that intermediate maturing varieties mature late should be corrected to the belief that intermediate maturing varieties have a strong reserve strength.

Planting intermediate maturing cotton varieties with a strong reserve strength should also be combined with corresponding techniques of cultivation. A strong reserve strength does not mean to let cotton grow blindly without limit. It must be combined with appropriate trimming, topping, removing the terminals of the branches to control horizontal growth and to control the growth of ineffective cotton bolls. The cotton plants of ordinary varieties with a strong reserve strength are relatively tall. The row distance should be appropriately widened or the plants should be planted in alternating wide and narrow rows. The method of fertilization should also be based on stimulating early development and steady growth to form more summer bolls so that the superiority of producing more autumn bolls can be fully developed.

2. Strong Resistance to Adversity

(1) During the seedling period, cotton can resist a lot of rain and low temperatures: The pattern of the need for water throughout the growth period of cotton is that it requires less water during the seedling period, more water during the budding and flowering periods and less water during the boll opening period. The physiological consumption of water during the seedling period (the first 10 days of May to the first 10 days of June) is about 50 millimeters, constituting about 15 percent of the whole growth period. According to meteorological data from 1955 to 1979 at Tianmen County, the amount of rainfall from the first 10 days of May to the first 10 days of June is 213.9 millimeters, four times the physiological need for water. The greatest amount of rainfall was in 1970, which amounted to 8.5 times, and the least amount of rainfall was in 1965, which amounted to 2.03 times. Also according to statistics of the Jingzhou Prefecture Meteorological Station (average from 1954 to 1980), the amount of rainfall during the same period was 193.9 millimeters, slightly less than that in Tianmen County. The average number of rainy days reached

17.9. The largest number of days reached 26 in 1973. Rainfall is not only plentiful during the seedling period, it is frequently accompanied by a cold front and low temperatures, thus weak seedlings, diseased seedlings, stiff seedlings and dead seedlings often occur seriously. To reduce the degree of damage by an abundance of rain and low temperatures, the most economical and effective method is to selectively breed varieties with a strong resistance to adversity. The Delta Pine No 15 and Eguang cotton varieties planted for a long period in the Jianghan Plain come from the southern part of the United States around 32°N latitude and cotton planting regions below 150 meters above sea level. This region is similar to the Jianghan Plain which is at about 31°N latitude and below 100 meters above sea level. The growth period of cotton is relatively close. But, the southern cotton planting region of the United States is near the Gulf of Mexico. It does not have the unfavorable weather of low temperatures, an abundance of rain and frequent cold fronts during the seedling period as does the Jianghan Plain. Therefore, the varieties selectively bred do not need to have a strong resistance to adversity during the seedling period. Therefore, the cotton varieties introduced from this region in the United States are not suitable for direct utilization in the Jianghan Plain. They should be modified so that they can gradually adapt to the climatic conditions of more rain and low temperatures during the seedling period. Varieties with a weak growth trend during the seedling period and with poor uniformity should be included as the major items for selective breeding.

(2) Tolerance to drought and waterlogging during the flowering and boll forming periods: In July and August, summer drought occurs frequently in the Jianghan Plain. At the same time, each year, drainage is poor because of torrential rains. Parts of the cotton fields are frequently affected by waterlogging. If varieties with a strong growth trend during the flowering and boll forming periods are planted, several more autumn bolls can be produced, and within a definite limit, this can reduce relative loss. The Jianghan Plain is situated in the alluvial plain along the two banks of the Changjiang and Hanshui rivers. Although there are sufficient water sources for irrigation, limited irrigation facilities must first guarantee the need for water for the more than several million mu of paddy rice. Also, most of the cotton fields as yet are still level over large areas but uneven in small areas, and the effectiveness of irrigation is poor. In addition, in Jingzhou Prefecture alone, there are 1.21 million mu of cotton fields which do not have sources of water. This requires that the cotton varieties have a stronger tolerance to drought and waterlogging.

3. Larger Total Number of Bolls per Mu

The yield of cotton consists of the number of bolls per mu, the weight of the bolls and the gin turnout. The abundance of the number of bolls is the foundation for high yields. In the Jianghan Plain, summer bolls are the basic factor that constitutes the yield of cotton. Therefore, striving for more summer bolls is the main direction to guarantee stable yields. But striving to produce several more autumn bolls on this basis is where the important potential for continually increasing the unit yield is, and this must not be overlooked.

4. Weight of the Boll Should Be Above 5 Grams

Viewing the breeding of cotton of the world's major cotton planting nations, we see that they all emphasize the selective breeding of large bolls. The Soviet Union is popularizing the Tashkeng No 1, 2, 3 varieties. These are crossed and bred from the large boll variety C-4727 as the main parents. The bolls of Tamcot and such varieties introduced into our nation in 1972 from the United States all have an average weight of over 5 grams. The weight of the boll of Lumian No 1, which has served importantly in cotton production in Shandong Province, is also over 5 grams. The weight of the boll of the Eguang cotton planted massively in our province averages only 4.32 grams in the 1978 and 1979 province-wide regional tests. Therefore, its yield cannot be easily increased. As we establish the goals of breeding, we should include the requirement that the weight of the boll should not be less than 5 grams as an important content. When making selections in the fields, we must grasp this requirement tightly.

5. A Gin Turnout of About 40 Percent

The ability of Delta Pine No 15 to be planted in China's Changjiang river valley and even widely in the Huanghe river valley for a time is inseparable from the characteristic of a high gin turnout of this variety. Our province introduced a massive amount of Eguang cotton in 1964 to replace the Delta Pine cotton No 15 because it had become impure and degenerated. At the time, increased yields were realized mainly because of the high gin turnout. When establishing the goal of breeding, the gin turnout should not be lower than the level of the original variety of Eguang cotton.

6. The Length of the Fiber Should Not Be Shorter than 29 Millimeters

The National Cotton Science and Research Conference held in 1978 established the criterion that the length of the fiber of cotton bred inland should not be less than 29 millimeters in main body length. This is suitable for the Jianghan Plain and it should be managed well. When making selections in the field, the length of the fiber should not be relaxed one bit.

In general, the goal of cotton breeding in the Jianghan Plain is to fully utilize the long growth period and the clear climate of the locality. Also, the goal should be to breed varieties which have a relatively strong adaptability to the abundance of rain and low temperatures during the seedling period, summer drought and high temperatures or waterlogging, and varieties that can produce several more good quality autumn bolls on the basis of early development and steady growth, thereby producing many summer bolls, so that the goal of truly producing more bolls, large bolls, a high gin turnout, long fibers and good quality fibers and high and stable yields can be realized. Only such new cotton varieties can make greater contributions to cotton production in the Jianghan Plain.

CROP DISTRIBUTION IN YUNYANG PREFECTURE REVIEWED

Huanggang HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 1, Jan 82 pp 13-16

[Article by Yi Fadong [2496 4099 2767] of the Yunyang Prefecture Agriculture Bureau: "Opinions on the Crop Distribution in Yunyang Prefecture"]

[Text] Yunyang Prefecture is located in the northwestern mountain regions of Hubei. The topography is complex. There are many types of agricultural crops. Food grain production is mainly wheat, corn and sweet potato. Geographic conditions vary. The climates in the north and south are different, and vertical climatic changes in the mountain areas are great. Agricultural production is limited by the climate and is very unstable. How can we suit measures to local circumstances in crop distribution and planting systems to combine using and nurturing the land, fully develop the superiority of stable yielding crops and achieve the goal of promoting benefits, avoiding damages, developing advantages and avoiding shortcomings? Several opinions concerning this question are presented here.

I. The Natural Conditions of the Yunyang Mountain Area and Agricultural Production

Only by correctly understanding the characteristics of the conditions of the soil, climate and water conservancy of the mountain region can we correctly guide agricultural production. Here, we will only talk about some of the relationships between the characteristics of natural conditions in our region and the planting of crops.

1. The mountains are broad but the land is narrow. The land is arid. There are many slopes. The land is infertile.

The whole region has a total area of 38.63 million mu of land, but there are only 3.68 million mu of arable land, a per capita of 1.4 mu. Of the arable land, 620,000 mu are paddy fields, constituting 16.8 percent. Dryland amounts to 3.06 million mu, constituting 83.2 percent, and 74.8 percent of this is slopeland. Most of the slopeland is precipitous and infertile. Agricultural production is widespread but harvests are poor. For example, in Zhushan County, the area of slopeland with a gradient larger than 30 degrees reaches 460,000 mu, constituting over half the area of cultivated land. The area of cultivated land with a soil layer less than 60 centimeters thick constitutes 35 percent. At the same time, the organic content of the soil is low. Nearly 600,000 mu of cultivated land has an alkaline dissolved nitrogen content below 100 ppm and 500,000 mu of cultivated land have a content below 10 ppm. Such serious lack of nitrogen, lack of phosphorus and infertility of the plowing layer is representative of the whole region.

2. Light and heat resources are relatively good and they are favorable to developing multiple cropping systems.

The number of hours of sunshine throughout the year in the Jianghan river valley is near 2,000 hours. It is 1,500 to 1,700 hours on Ergaoshan at 500 to 900 meters above sea level, 500 hours more than that in southwestern Hubei. The total amount of annual radiation is 107 to 111 kilocalories/square centimeter, more than that in southwestern Hubei and the Three Gorges of Changjiang by 11 percent and 6 percent respectively. The average daily amount of heat throughout the region from April to October is 250 to 450 calories, 73 calories more than that in Hangzhou. The active cumulative temperature ≥ 10°C is 4,500 to 5,200°C, 50 to 120°C more than that in Xinyang and Bangfu on the same latitude. The number of days over the years with an average temperature ≥ 12°C is 196 to 214 days, and the number of days over the years with an average temperature ≥ 20°C is 104 to 123. The beginning day with a temperature ≥ 10°C in Yun County north of the Jianghan (Plain) averages to be 25 March, the same as that in the Jianghan Plain. The rich amount of heat resources has provided conditions for developing double and triple cropping. In 1980, double cropping areas of paddy fields throughout the region have already expanded to 397,000 mu, and the area of triple cropping in dryland has expanded to 730,000 mu.

3. Agricultural production is visibly affected by the vertical climates. Distribution of agricultural crops is diversified.

Taking the Jianghan Plain as the border, the annual average temperature in Yun County, Yunxi and Jun County (abbreviated as the three northern counties) is 15.4 to 16°C. The annual average temperature in Zhushan, Zhuxi and Fang County (abbreviated as the three southern counties) is 14.3 to 15.6°C. The frostless period in the three northern counties is 15 to 30 days longer than that of the three southern counties. The amount of rainfall in the three southern counties is 130 to 190 millimeters more than that in the three northern counties. The vertical climates in the mountain region visibly affect agriculture. The elevation of the valley of the Changjiang and Hanshui rivers is less than 100 meters above sea level. The "first peak in Central China" has an elevation of 3,052 meters above sea level. Each increase of 100 meters in elevation above sea level is marked by an average drop of approximately 0.55°C in temperature. The cumulative temperature ≥ 10°C lessens by 150 to 190°C. The frostless period shortens by 7 to 9 days. The growth period of crops is delayed by 4 to 5 days. The amount of rainfall increases by 35 centimeters in the low mountain areas and by 53 centimeters in the high mountain areas. The vertical change in climate has formed three-dimensional ecological types, such as wheat at low elevations and potatoes at high elevations, potatoes in the south and yams in the north and mandarin oranges in the north and lacquer [trees] in the south.

4. The distribution of rainfall is uneven. There are many disasters. The degree of stable agricultural yields is not high.

The mountains are large and the valleys are narrow in our region. Water conservancy resources are rich. The whole region has a hydroelectric reserve of 500,000 kilowatts. The present water conservancy facilities number over 37,000 locations. They store, draw and lift an effective amount of 450 million square meters of water. But the small hydraulic stations do not have complete facilities. The effectively irrigated area is only 550,000 mu. Of the 3.06 million mu of dryland, the irrigated area is less than 60,000 mu. Annual amount of rainfall is 800 to 1,150 millimeters. Distribution is very uneven. There is more rainfall in the three southern counties and less in the three northern counties, and more in the high mountains and less in the low-lying mountains. Summer rainfall constitutes 41 to 46 percent of the amount of the whole year. Most of this rainfall comes down as torrential rains and they frequently cause mountain floods. At the same time, there is more autumn rain than spring rain. Winter rainfall constitutes only 4 to 6 percent of the annual amount of rainfall. Therefore, drought, waterlogging, low temperatures, ice and hail, and mountain floods occur almost every year. Summer and autumn drought have an especially high probability of occurrence, and they severely damage agricultural production. For summer and autumn crops, summer harvested crops suffer fewer disasters and produce stable yields. Autumn harvested crops suffer more disasters and produce unstable yields.

II. Fully Develop the Superiority of Stable Yielding Crops, Guarantee the Steady Increase in Food Grains and Economic Crops

Never slacken food grain production and actively develop diversification are the correct policies for developing agricultural production. Specifically in the mountain regions of Yunyang, success was achieved by self-sufficiency, having a surplus of food grains and developing diversification in a big way. In recent years, especially since the 3rd Plenary Session of the 11th Party Central Committee, agricultural production of the whole region has broken away from the lingering situation which lasted for 10 years. Development was relatively fast. During the 5 years from 1976 to 1980, production of food grains increased for 4 years consecutively. By 1979, the region basically realized self-sufficiency. This has served greatly in stabilizing the economic trend in farm villages and in developing diversification centered around forestry and the production of handicraft products. But, because of natural disasters and the weak ability to fight disasters, food grain production was very unstable. Practice showed that although the conditions for developing diversification in the mountain regions were good, if food grains were insufficient, diversification and economic crops could not be developed well. At the same time, land resources cannot be increased. Destroying forests to reclaim and expand the planting area for food grains will cause the destruction of forest resources and soil erosion will worsen. The only practical and correct way is to adapt to the climatic patterns, fully develop the superiority of stable yielding crops to increase yields, improve the multiple planting index, and improve unit yield under the prerequisite of stabilizing the area of planting.

1. Fully Develop the Superiority of Summer Grains

Winter in the Yunyang Prefecture is relatively warm. Rain and snow in ordinary years amount to less than 50 millimeters. The amount of rainfall during the growth period of wheat is generally 330 to 360 millimeters, suitable for the needs to cultivate high yielding wheat. For example, from the first 10 days of October to the last 10 days of December, the cumulative temperature above 0°C is 987°C in Yun County and 834°C in Fang County. The final day with an average daily temperature of 3°C is 20 December in Yun County and 10 December in Fang County. Wheat sown during the middle and last 10 days in October has an effective tillering period of over 50 days in the three northern counties and 40 to 50 days in the three southern counties. The peak tillering period of November has an average temperature of 10.5°C in Yun County and 8.9°C in Fang County. The amounts of rainfall in the two counties are 39.7 millimeters and 36.4 millimeters respectively. Therefore, the temperatures and rainfall are very favorable to tillering of wheat. The beginning day when the temperature steadily passes 20°C is 19 May in Yun County and 29 May in Fang County. High temperature forced heating during the filling and maturation periods occurs very infrequently in ordinary years. During the latter period of wheat growth, although the amount of rainfall during the two months of April and May is more abundant in Fang County (173.8 millimeters), waterlogging may occur in paddy fields and flatland, but seldom occurs in wheat fields on slopeland. As long as the "three ditches" are dug well in flatland, waterlogging can be reduced or avoided. Therefore, summer wheat not only produces a stable yield, but managing cultivation well can also produce over 400 min per mu in yield.

Summer food grains occupy a very important position in our region's food grain production. During the 31 years from 1949 to 1980, there were 17 years in which summer increases brought about an increase throughout the year, and there were 8 years in which a summer reduction in yield brought about a reduction in yield throughout the year. There will be a stable and reliable foundation only if we can use summer yields to stimulate autumn yields and to produce a bumper harvest for the whole year. In recent years, the proportion of summer food grains throughout the region has continued to increase. The proportion of summer food grains now basically constitutes one-third that of the whole year. The proportion of summer food grains at some communes and brigades with larger areas of cultivated land has already reached 40 to 50 percent. For the whole region, the proportion of summer food grains can still be appropriately increased to 35 to 40 percent. Among the summer food grains, planting of wheat should be mainly expanded. The yields of broad beans and peas are not high and not stable because of the effects of overcast and rain and low temperatures during the flowering periods. Their planting areas have lessened from 400,000 mu to 270,000 or 280,000 mu. But the crop opening of broad beans and peas is early and good. The people also need such early and good crop openings in daily living, therefore their planting areas should not be reduced further. The summer food grain crop that should be developed in the high mountain region is mainly potatoes. Cold high altitude mountain regions over 1,000 meters above sea level are appropriate for developing early maturing wheat.

2. Fully Develop the Superiority of Spring Sown Corn

The yield of corn in Yunyang Prefecture constitutes about one-third the total annual yield of food grains. It occupies the same important position as wheat. But, in continuous cropping of wheat and corn and destroying the crop opening for sowing, the advancement of staminate and dispersion of pollen of corn meet the drought (bottleneck drought) at the end of July and the beginning of August. A slight drought reduces yield and a severe drought can eliminate the entire harvest. The yield is very unstable. To improve the degree of stability of the yield of corn, continuous cropping and destroying the crop opening must be changed to companion planting of wheat and corn. Corn should be sown in the spring. This will develop the potential of the climatic resources to increase yield and will also stimulate the advantages and prevent damages. The intermediate and late maturing corn varieties Yundan No 1, Zhongdan No 2 currently being propagated in our prefecture require about 75 days from sowing to staminate advancement. If corn is sown at the beginning of April in the low mountain regions and during the first 10 days of April in the Ergaoshan area, the period of staminate advancement will fall within the rainy period, and this can effectively prevent "bottleneck drought." But sowing cannot be completed within 3 to 5 days in large area production. Therefore, sowing should begin about 20 March in the low mountain areas and around 5 April in the Ergaoshan area. The end of sowing in the high mountain areas should not be later than 20 April.

3. Fully Develop the Superiority of the Sweet Potato, A Disaster-resistant Crop

In recent years, the planting area of sweet potatoes throughout the prefecture has been about 750,000 mu. The yield constitutes about 15 percent of the total yield of food grains. The amount of rainfall in the three northern counties is less. Drought is outstanding. Eighty percent of the area of sweet potato plantations of the whole prefecture is concentrated here. But, as interplanting and companion planting develop and as the crop distribution changes, the planting area of sweet potatoes during the past 2 years has decreased. Viewing the whole prefecture, relative stability of the planting area of sweet potatoes should be maintained in the future to improve unit yield. The potential of unit yield of the sweet potato is great. Transplanting sweet potatoes in spring and summer, even when spring drought and summer drought occur and affect vegetative growth, can still produce relatively ideal yields after autumn rain. Sweet potatoes must be rationally distributed in arranging the crop opening. In addition to leaving a portion of fallow land that needs to be plowed under in spring for planting sweet potatoes, continuous cropping of soybeans and sweet potatoes and companion planting of wheat and sweet potatoes can also be carried out.

4. Fully Develop the Superiority of Paddy Rice Which Is a Stable Yielding Crop

Except in the high mountain regions, our prefecture's paddy fields are mainly double cropping wheat and rice fields (during the past 2 years, some areas have developed double cropping of rape and rice). A number of brigades producing a per mu yield of 1,400 to 1,500 jin of double cropping sheat and rice have emerged. But because small water conservancy projects are not complete, in recent years the area of transplanting has lessened. Each year, only 520,000 to 550,000 mu have been transplanted. Also because of the backwardness of the technology of cultivation, the quality of transplanted seedlings is poor. They do not develop early. And with the epidemic of rice leaf hoppers that has caused a disaster, production of paddy rice has developed slower than the production of dryland food grain crops. But for the people's livelihood and stable yields of crops, production of paddy rice should be greatly developed in the future. Localities with water sources should expand the area of paddy fields.

The development of double cropping of wheat and rice leaves a large area for the late crop. Late transplanting of ordinary rice will not easily produce high yields. Hybrid paddy rice must be actively propagated to raise the production of paddy rice to a new level.

5. Suit Measures to Local Circumstances to Develop Economic Crops

The per capita income of commune members in our prefecture is very low. In 1980, per capita income was 69 yuan. There are also 22.6 percent of the production teams which have a per capita income of less than 50 yuan. Less income for the commune members and insufficient capital for reproduction make it difficult to elevate scientific and technological standards. Therefore, while steadily developing food grains production, we must fully utilize the superiority of the mountain regions to develop timber and economic forests in a big way, and within the planting sector, we must develop economic crops actively and according to plan.

The distribution of economic crops must also be done by suiting measures to local circumstances. The humidity in the three southern counties is high. The temperatures are lower than those in the three northern counties. Bast fibers can be developed. Except for a small number of river valley regions where the microclimate is good, overemphasis on the development of cotton should not be done.

The mountain region has had a long period of shortage of edible oil. The production of oil bearing crops should be developed according to plan. The high mountain region also has a future for development. For example, the Longguang No 1 Brigade of Liudou Commune in Yunxi County planted 2.5 mu of cabbage-type rape in 1980. Seedlings were cultivated during the middle 10 days in July. They were transplanted during the first 10 days of September. Average per mu yield was 331 jin. The cultivated areas in the northern parts of Jun County and Yun County are larger. While developing summer food grains, we should actively expand the planting of sesame. To adjust the crop opening and increase the source of fertilizers in the double cropping region of wheat and rice, we should appropriately develop double cropping of rape and rice. Fifteen to 20 percent of the paddy fields can be arranged each year for planting rape. In addition, each locality can also utilize unused land between forests to plant peanuts. Localities with favorable conditions can develop the triple cropping system of wheat, corn and peanuts.

The crop opening of tobacco is good. The economic value of tobacco is high. The old producing regions in Jun County should actively revive the production of their famous dried tobacco. Yun County and Yunxi can suit measures to local circumstances to develop Maryland tobacco and aromatic tobacco. Zhushan and Zhuxi can develop mao ba tobacco. Transportation is inconvenient in the mountain regions. Transporting coal for curing tobacco is difficult. In the future, flue cured tobacco should not be developed.

The humidity of the regions above Ergaoshan is high. Over the years, this region has a tradition of planting soybeans. During the 1970's, the yield of soybeans of the entire region once reached over 70 million jin. In recent years, because of the development of companion planting of wheat and corn and potato and corn, the area of pure soybean plantations has gradually lessened, and the yield is less than 40 million jin. In the future, in addition to actively developing the triple companion crops of wheat, corn and soybeans, some of the frontier infertile land where the yield of companion planted corn is not high should be changed to companion planting of wheat and soybeans.

III. Insist on Developing Interplanting of Mainly Companion Planted Wheat and Corn

Interplanting and companion planting of mainly companion planted wheat and corn have broken away from the limitations of the continuous cropping system and have opened a broad road for improving the multiple planting index. They suit the natural conditions of our prefecture, which has less rain and many disasters, drought in 9 out of every 10 years and several droughts in a year, and they suit the productive conditions of our prefecture which has more slopeland and less flatland, more dryland and fewer paddy fields, and a weak ability to resist disasters. Many years of practice show that the development of agriculture in the mountain regions and the stady increase in food grains can be realized by developing stable yielding spring and autumn sown crops to seek high yields in stable yields.

Since 1975, the whole prefecture has developed companion planting of wheat and corn and potatoes and corn. Preset rows for autumn sowing cover more than 1 million mu each year. This enables the sowing period of corn to begin generally 50 to 60 days earlier, while expanding the area of summer food grains continuously. The staminate advancing period correspondingly occurs earlier. The threat of summer drought in the low mountain regions has thus been greatly reduced, and the high mountain regions can avoid autumn cold. The area of summer food grains in 1979 throughout the prefecture showed an increase of 460,000 mu over that in 1975. The yield increased by 267.29 million jin. Net increase of corn was 230.94 million jin. The total yield of food grains of the whole year increased by 547 million jin, an increase of over 47 percent. Also, corn was companion planted. Because the side rows of wheat constitute 50 percent of the whole field, the preset rows form a ventilation and light permeation "corridor." The characteristics of the spikes of wheat improved. At 5.5 chi per strip, the preset row is 2.5 chi, the sowing width of wheat is 3 chi, and the per mu yield can reach over 600 jin.

Companion planting of wheat and corn is an important measure to guarantee that the crops are rationally distributed as described above. During a defninte period in the future, we should insist on developing it and keeping it stable. Except for the regions where paddy fields are concentrated and where there are fewer people and more land, the areas of companion planting at most localities should be expanded. The method of companion planting should be rationally arranged according to the texture of the soil and the distribution of the forecrop and the aftercrop. At present, the preset rows are generally too narrow and are not up to standards. They require urgent improvement. Viewing the whole prefecture, the following methods are better:

(1) Six chi for each strip. The width of sowing wheat should be 3 chi sown in five to six rows. The preset rows are planted with two rows of corn with a small row of 1 chi. The distance between plants should be 8 cun, 2,500 plants per mu. This is suitable for use in plots with intermediate and low soil fertility.

(2) Eight chi per strip. The sowing width of wheat can be 4 chi shown in seven to eight rows. The preset rows can be three rows of corn with a distance of 8 cun between plants, 2,800 plants per mu. This is suitable for plots with intermediate soil fertility.

(3) Ten chi per strip. The sowing width of wheat can be 5 chi sown in seven to eight rows. The preset row can be 5 chi. Low earth mounds can be made to transplant two rows of sweet potatoes. One row of corn can be companion planted between rows. After harvesting wheat, the crop opening is destroyed to plant sesame. This is suitable for regions mainly planted with spring sweet potatoes.

(4) Companion planting of potatoes and corn can popularize the method of 5 chi per strip. Potatoes can be planted in narrow rows of 1 chi. The preset row can be companion planted with two rows of corn.

In addition, interplanting and companion planting can also be done for companion planting of food grains and green manure crops, such as presetting rows for companion planting of winter green manure at autumn sowing, companion planting of tamarix fiber after harvesting wheat and companion planting of tamarix fiber or mung beans after harvesting early corn, plowing green manure plants under as base manure for autumn sowing. These should be actively tested and popularized to combine use and nurturing of land. The double cropping regions of rice and wheat have fewer paddy fields and more laborers. To fully develop the function of increased yields of good fields and good soil, we can cut green plants as cumulative fertilizers, return stalks to the fields and establish year-round green manure bases on mountain slopes to nurture the land. Pure green manure should not be overly planted. Of course, it is necessary to appropriately change some of the double cropping wheat and rice fields to double cropping rape and rice fields. Rape is an oil-bearing crop and a fertilizer crop. At the same time, its crop opening is earlier than that of wheat, and it can benefit paddy rice production.

CONTRACT SYSTEM FOR VEGETABLE PROCUREMENT PRAISED

Nanjing XINHUA RIBAO in Chinese 16 Feb 82 p 1

[Article by Yang Lixin [2799 4539 2450] and Wei Laihong [7279 0171 1347]: "Nantong Municipality Comprehensively Promotes Vegetable Production and Marketing Reward and Penalty Contract System. Adheres to Planned Growing to Assure Phased Market Arrival"]

> [Text] Editor's Note: Vegetables are a commodity that everybody needs everyday, but vegetable production and supply are frequently difficult to control. As a result, production and marketing contradictions are fairly prominent. How can these contradictions be solved? Nantong Municipality's experiences have demonstrated that institution of a vegetable production and marketing reward and penalty contract system is an effective method.
>
> The situation everywhere shows that if vegetable production and supply are to be improved, it will be necessary to strengthen planning and persevere in planned planting to assure balanced market arrival. This planning requires strict contracts as a guarantee. Without contracts, planning has no guarantees and may fail to deliver. To fulfill contracts is to carry out plans. In order to strengthen planning concepts and guarantee benefits to vegetable producers, dealers in vegetables, and the broad masses of consumers, we must intensify ideological training and, at the same time, genuinely take in hand the task of vegetable production and marketing contracts.

Nantong Municipality's general promotion of vegetable production and marketing systems have put vegetable production and marketing work on the path of national planning and have promoted vegetable production and supply. At the present time, throughout the municipality, all vegetable production teams are in the process of further strengthening care of vegetables in the field are are devoting attention to preparations for spring farming and production, striving to make vegetable supply during the spring period of shortage better than in former years.

Formerly, because of insufficient clarity about economic responsibilities in vegetable production and supply, Nantong Municipality's farming and business sectors wrangled with each other, with the result that planting plans were difficult to implement; phasing of supplies sent to market was difficult to achieve; improvement in vegetable quality was difficult; it was difficult to determine price according to quality, and the masses' displeasure was considerable. In view of the aforestated problems, Nantong Municipality proceeded from success in the operation of pilot projects, beginning in October 1981 to organize the municipality's 174 vegetable production teams and the urban area's four vegetable procurement stations for all-around implementation of production and marketing contract systems. Contract provisions took simultaneous account of the interests of the state, the collective and individuals, and embodied the principles of equality and mutual benefit and compensation at equal value for both producers and marketers. Emphasis centered on planned planting, phased market deliveries, vegetable quality, and stable prices, responsibility for these four matters being placed on both producers and marketers in the institution of a contract system of rewards and penalties that linked vegetables, money and grain. Following certification by municipal industrial and commercial administrative and management units, they were put into effect.

More than four months of experience has shown that practice of a contract system of rewards and penalties for vegetable production in which awards and penalties, rewards and punishments are clearly set has aroused the enthusiasm of both producers and marketers. Specific benefits are manifested in the following three regards.

First, it has promoted planned planting and planted deliveries to markets. Contracts clearly stipulate that if vegetable teams do not plant according to plan, they may not dispose of any excess portions planted as they see fit, and they will not enjoy a premium price for deliveries to market or a premium price for quality that vegetable companies may pay at the time of procurement in accordance with prevailing market prices. For reduced planting or unplanted portions, they will be fined 10 percent of the per mu output value of similar varieties sent to market. If vegetable stations fail to discuss planting plans with vegetable brigades and put them into effect on time, thereby causing delays in the farming season, or if vegetable stations demand changes in plantings after vegetable production teams have planted according to plan, vegetable stations will be liable to indemnify vegetable brigades according to the actual losses they have sustained. This method maintained the solemnity of planting plans. In addition, a method of dovetailing production with planned deliveries to market was formulated. All vegetable teams delivering vegetables to markets for sale according to plan received bonuses. Reduced deliveries or failure to deliver resulted in commensurate forfeiture of grain and money as punishment, thereby effectively guaranteeing planned planting and phased market deliveries. Many vegetable teams took scales into the fields and weighed vegetables before sending them to market so that vegetables offered for sale were neither too many nor too few. They have surmounted a situation on vegetable farms of sometimes too much and sometimes too few vegetables, and the rotting of vegetables when there have been too many or a shortage of supply when there have been too few. Now an average 9.6 liang of vegetables per capita are supplied daily to the city. This plus the amount sent to markets in the country fair trade substantially satisfies the needs of the masses.

Second was improvement in vegetable quality. According to the terms of contracts, vegetables delivered to market that meet first and second grade standards earned a premium price from the company. If these standards were not met, not only was no premium price paid, but a fine was levied. As a result, vegetable team quality concepts were intensified. After some vegetable teams sent vegetables to market that did not meet grade requirements, they did more work in the markets to straighten matters out. More than 96 percent of the vegetables sent to market between October and December 1981 were of first or second grade, and this was vastly higher than contract requirements stipulated.

Third was improvement in relations between agriculture and business. Formerly arguments between the agricultural and the business sector occurred about prices. Vegetable stations felt that vegetable teams made deliveries to market with an eye on prevailing market prices, and vegetable teams accused vegetable stations of setting prices on the basis of the market situation. In view of these circumstances, contracts emphasized the honoring of price policies. No matter whether during seasons of shortage of abundance, agreement about price had to be done on the basis of quality. In case of conflicts, discussions should be held to find a solution. If discussions did not succeed, higher authority or units concerned would be asked to set a price. In cases where quarrels resulted in delays or caused vegetable losses, the party at fault would bear responsibility. Any willful downgrading of quality in order to beat down prices, or inflating quality to raise prices would also result in fines. Thus, both the agricultural and the business sector had rules to go by and agreements to rely on. In cases of conflict, means existed to solve them, and if contracts were violated, blame could be fixed, thereby avoiding mutual arguments and mutual recriminations.

AFFORESTATION AIDS DESERT CONTROL

OW130306 Beijing XINHUA in English 0255 GMT 13 May 82

[Text] Yinchuan, 13 May (XINHUA)--Afforestation in Zhongwei County, Ningxia Hui Autonomous region, has forced the Tengger Desert to retreat 10 kilometers northward in the past 33 years.

The county which is on the southeastern edge of the desert has always been plagued by sandstorms. Records show that for the past 400 years from the Ming Dynasty up to the founding of New China the desert advanced southward at a rate of 5 meters a year. Dust storms swallowed up farmland and levelled villages.

The local government has mobilized the people to take part in afforestation campaigns every year since 1949. They also built crisscross fences made of dry wheat stalks to anchor the sand dunes and conducted water from the Yellow River to irrigate the sandy soil. After almost 33 years of hard work, a shelter belt 60 kilometers long covering 6,300 hectares has been formed. Trees planted along roadsides, ditches and around houses number 9,380,000. The state has allocated special funds annually for the project and scientific research units have sent groups to the county to help the local people plan the desert control work.

Zhongwei County now has 26,000 hectares of cultivated land, more than double that of 1949. Total grain output last year was 101,400 tons, five times what it was in the early years of New China.

MUPING COUNTY SPRING FARMING--Spring farming is being carried out speedily and in good measure in Muping County, Shandong Province. The county has irrigated 150,000 mu of wheatfields, plowed and leveled 230,000 mu of fields and begun construction of 351 irrigation projects. Ninety-seven percent of the county's brigades have instituted the responsibility system of setting payment according to output. Many people have been able to engage in diversified production. The income from the diversified economy from January to March was 15.4 million yuan, 33 percent more than in the corresponding 1981 period. [SK292229 Jinan Shandong Provincial Service in Mandarin 2300 GMT 27 Apr 82 SK]

CADRES COMBAT DROUGHT--Over 10,000 cadres in Weifang Prefecture have gone to the forefront to help combat drought. So far this prefecture has watered 4.84 million mu of wheat and sown 5.13 million mu of spring crops, which accounts for 79 percent of spring sowing acreage. The sowing of field crops, except for sweet potatoes and peanuts, has basically been completed. According to statistics, this prefecture has carried out 10,500 water conservancy projects and completed 8,300 of them, sunk 7,670 machine-operated wells and 131,400 indigenous wells and expanded and improved 567,000 mu of irrigated land. [SK120824 Jinan Shandong Provincial Service in Mandarin 2300 GMT 11 May 82 SK]

RAINFALL REPORTS--Rain fell in 35 municipalities and counties in Shandong Province on 10 May. In the early morning of 11 May, rainfall measuring 10-31 millimeters in nine counties and cities including Huimin, Zouping, Hauntai, Qingyun, Weifang, Anqiu, Qixia, Zhaoyuan and Beizhen, and below 10 millimeters in the remaining 26 counties and cities was recorded. Spring field crops are being sown on a crash basis in these localities. [Jinan Shandong Provincial Service in Mandarin 2300 GMT 11 May 82 SK]

QUOTAS FOR GRAIN PURCHASE, SALE, ALLOCATION REVIEWED

Circular Issued

Taiyuan SHANXI RIBAO in Chinese 26 Feb 82 p 1

[Article: "Provincial People's Government Circular on Quotas for Purchase, Marketing and Transfer of Train This Year"]

[Text] The provincial people's government recently issued a circular requesting people's governments at all levels to adopt quotas for the purchase, marketing and transfer of grain starting in 1982. Quotas once fixed will remain unchanged for 3 years.

The circular specifies the following:

1. Appropriate to different forms of rural responsibility in production, localities should see to it that the purchase quotas are fixed for all contracting units including production teams, labor groups and households. Contracts should be signed for this and the quotas should remain unchanged for 3 years. In-depth investigation should be made to ensure that the quota burden is equitably distributed. Quotas for the purchase of surplus grain should be based on the ability to provide commodity grain and must not be distributed equally. Contracting units may sell their surpluses at higher prices only after they have fulfilled their base purchase quotas.

2. Grain marketing quotas which the province allocates to various lower units do not include grain used for fostering production and rewarding cottongrowers. Grain marketing quotas cover the following: food grain for fixed population, supplies to staple- and nonstaple food industries, supplies to the brewery industry, grain for use by public services and industrial enterprises, animal feed, grain for fattening pigs, grain to sell back to the countryside, grain as reward for the sale of farm and sidelines products, grain for making up seed supplies, and grain as subsidies for public project laborers. With the adoption of the rural responsibility system in production and the liberalization of rural economic policies, grain-short teams should be able to find their own sources of grain supplies to make up their shortfalls and should no longer be supplied by the state in normal years. Teams and households that are really in need of grain can borrow grain from the state and return it the following year. Grain shall be borrowed and returned at the same price as

grain purchased by the state. Vegetable, fruit and cash-crop growers who have fulfilled the state plan but are short of food grain shall be supplied with grain in amounts either according to existing provisions or according to fixed marketing quotas which will remain unchanged for 3 years.

3. Localities should give an overall consideration to quotas for the purchase and marketing of grain. They should consider local conditions, arrive at reasonable quotas amount of grain to be purchased and marketed during the year, liven up the local grain economy, balance a good crop year with a bad crop year, make up the deficit of a bad year with the surplus of a good year. They may purchase more grain in a good year and less grain in a bad year. They must adhere strictly to the difference between the amount purchased and the amount marketed as specified for them by the province. Localities required to export grain must not reduce their export; localities that import grain must not increase their import. Provided the difference is observed between the amounts transferred in and out, localities may make mutual adjustments to their grain purchase and marketing quotas. When they need to market more grain they must purchase more. When they are sure they will market less grain they may purchase less. A settlement of account should be made once every 3 years. Localities that have purchased more than they have marketed may retain the surplus for use in lean years. Localities that are short of grain due to natural disasters or other causes must find additional supplies themselves. Grain borrowed from the province in a year of severe calamities must be returned later.

4. To meet the needs of a developing national economy, the needs of the armed forces and the cities and the needs of the market, quotas for the transfer of soybeans, millet, assorted beans and sorghum should be increased. The types of such grains and their amounts shall be specified every year by negotiation between the grain administrations and localities. Wheat transferred out of a locality for use as a reward to cottongrowers of another locality can count as wheat transferred by the contributing locality to a higher unit, but shall not count as part of the regular wheat transferred into the recipient locality. When localities have fulfilled their quotas for transfer to the higher units, any surplus or deficit against the purchase and marketing quotas will be balanced by the province.

5. With the introduction of quotas for grain, the general principles, policies and regulations on grain should continue to be observed. Localities should not under their own authority make changes to the following: the range of price increases for the purchase of surplus products, the state and provincial policy regarding the award of grain for the sale of farm and sideline products, the transfer of rural inhabitants to urban areas, the amounts of grain to be supplied to people in cities and towns, and the regulations on the management of grain prices. With the exception of the grain which localities can market at negotiated prices, all grain stored in prefectural and city granaries is only at the disposal of the state, and must not be touched without the approval of the provincial authorities.

6. End of March grain inventories at localities to be used against outstanding national and provincial grain coupons shall be treated temporarily as revolving stocks of the prefectures and cities (a reasonable level of their

stocks will be determined later). Starting from 1 April 1982, grain coupons will count as grain transfers and will be settled together with grain transfers. Drawing on grain coupons will be like transferring in grain, delivering grain coupons to a higher level will be like transferring out grain.

7. The 50-50 ratio provided by the province for grain sold at negotiated prices will remain unchanged. Localities should promote the purchase and sale of grain at negotiated prices, balance surpluses and deficits, liven up the market, keep grain prices down, and treat the purchase of negotiated-price grain as a supplementary source of grain for the state.

8. Base purchase quotas for localities as approved by the State Council must not be changed without the approval of the State Council. Starting from 1982, the percentage of the base purchase quotas to be fulfilled by localities should be fixed on the basis of the actual fulfillment by localities in the past 2 years. Specific methods of arriving at the percentages shall be announced by the grain administrations.

The circular points out that the quotas for the purchase, marketing and transfer of grain represent a major reform of the system of grain management. It involves many policies and touches many sectors of society. It affects directly the development of grain production and the livelihood of the people in town and in the countryside. The people's governments at all levels must give the matter full attention and use their best efforts to carry out the reform.

Commentary on Monopoly

Taiyuan SHANXI RIBAO in Chinese 26 Feb 82 p 1

[Commentary: "With Planning as the Mainstay, Carry Out State Purchase and Marketing of Grain"]

[Text] The use of fixed quotas for the purchase, marketing and transfer of grain by the state is a major reform in the country's management of grain. It is beneficial for the continued stabilization of the peasants' burdens and the growth of farm production. Within the framework of a balanced supply and demand of grain a rational readjustmenttof the geographical pattern of farm crops brings greater initiatives from the central authorities, the localities and the grain administrations. All localities must take earnest steps to carry out this reform.

Fixed quotas for the purchase, marketing and transfer of grain by the state must be based on economic planning supplemented by market readjustment. The principle of planned purchase and marketing must be adhered to. We must give things overall consideration and make arrangements for everything involved, handling in a correct way the relationship between the state, the collective and the individual. We must do our best to narrow the gap between grain receipts and outlays. We must not pay attention only to small things and lose sight of bigger things, pay attention to individual interests and lose sight of the interests of the whole country. In fixing the quotas for the purchase, marketing and transfer of grain, some localities wish only that they could sell less grain to the state, retain more and sell less of the better varieties, buy more and better varieties from the state, and sell at a higher price to make the peasants happy. Some localities, because they have contributed less grain to the state due to natural disasters in the past 2 years, want to have lower quotas; they fail to see, from a developmental point of view, what productive enthusiasm has been aroused from the masses since the introduction of the rural res system of production. A few comrades wish their localities could have more flexibility by selling less to the state and selling more to the consumers. All this means that the relationship between the state, the collective and the individual has not been treated properly, and local interests have been stressed at the expense of the interests of the country as a whole.

Are there really difficulties in fulfilling the quotas? We believe that in our province the difficulties, although they exist, are not too great. Since the introduction of the rural responsibility system in production, farm produce has increased substantially, and the percentage of purchase quotas has declined a great deal during the last few years. For example, the percentage of purchased wheat has dropped from about 25 percent to around 13 percent in recent years. In 1981, 16 million jin of soybeans were purchased in the province at the fixed price, or 39.8 percent of the purchase target, but 34 million jin were purchased at negotiated prices. Six million jin of asserted beans were purchased at the fixed price, or 35 percent of the purchase target, but 35 million jin were purchased at negotiated prices. It is not that it was impossible to fulfill the purchase quotas but certain people wanted to sell at higher prices. On this question of fixing quotas for the purchase of grain we must educate the peasants and make them see that the state has done its utmost over the past 3 years to take care of their interests and that they should on their part take the interest of the whole country into consideration by fulfilling the grain purchase quotas to support the cities, the industries and national construction.

Doing a good job of grain distribution and livening up the grain economy on the basis of planned purchase and marketing by the state--this is an important task for the grain administrations and an honorable duty for party committees and people's governments at various levels. To assure fulfillment of the quotas for the purchase of grain and surplus grain, production teams, labor groups and households should all have fixed quotas. When they have fulfilled them, they may dispose of their surplus grain as they see fit. The state can negotiate with the teams and peasants for purchasing the surplus grain at negotiated prices. In localities where it is feasible, fine grains and industrial products can be used to exchange with the teams and peasants for grain. This will supplement the state's quota purchases in meeting the basic grain needs of various sectors.

Setting quotas for the purchase, marketing and transfer of grain is new work. The leadership at various levels must take it in their own hands, strengthen public information, conduct in-depth investigations of conditions in the communes and brigades, and do their best to arrive at a fair distribution of quotas. Grain administrations under the leadership of the governments at various levels should pay full attention to the fixing of quotas this year. All localities in the province must complete the fixing of quotas for all contracting units before the "Grain Rain" season.

PROVINCIAL LEADERS INSPECT KEY UNITS

HK140613 Taiyuan SHANXI RIBAO in Chinese 6 May 82 p 1

[Report: "Provincial CCP Committee, Government Leading Comrades Go Down to Key Enterprises To Solve Problems on the Spot, Promote the Development of Production"]

[Text] Recently, Wang Kewen, secretary of the provincial CCP committee, and Wang Xi, vice governor, led responsible members of the economic committee, the planning committee, and responsible members of the industrial and communications, and financial and commercial departments and bureaus, to the Taiyuan Steel Works and 14 other large and medium-sized factories and mines. There they held discussions with comrades of the enterprises and solved 59 urgent practical problems, thus promoting the development of current industrial production.

The total industrial output value of these 15 factories and mines accounts for a very great percentage of the total industrial output value of the Taiyuan area. Most of them fulfilled or overfulfilled their production quotas of the first quarter of this year. In the second quarter, they all have encountered some problems which are relatively difficult to solve. Some of these problems involve the relationships with the commercial, supply and transportation departments. Delay in solving these problems due to disputes over trifles or red tape could possibly affect the increase of economic returns. After responsible members of departments concerned, headed by leading comrades of the provincial CCP committee and provincial government, arrived at these enterprises, they adopted the method of "joint examination by responsible members at three levels and making on-the-spot decisions." This strengthened economic coordination and some problems which had remained unsolved for a long time were readily solved. In the Xishan Mining Bureau, for example, production was affected due to overstocking of coal. After the arrival of responsible comrades of the provincial government, a "joint examination" by responsible members including those of the provincial economic committee and the Taiyuan Railway Bureau was held on the spot. It was finally decided that the Taiyuan Railway Bureau should make sure that 550 railway cars would be provided every day. The problem of gasoline for some 100 trucks was also solved. This not only ensured that all the coal to be produced this year would be transported to other places but a portion of the overstocked coal would also be transported. The problem of overstocking of coal was thus basically solved. Besides, they also handled official business on the spot and helped the Shanxi Textile Printing and Dyeing Mill, the Taiyuan Pharmaceutical Plant, the Taiyuan Chemical Fertilizer Plant and the Taiyuan Chemical Works solve problems of raw material supplies of 50 tons of caustic soda, 16,000 tons of coke, 14 tons of diesel oil and 10 tons of acetone.

As a result of responsible members of departments concerned, headed by responsible comrades of the provincial CCP committee and the provincial government, handling official business on the spot, the relationships between industry and commerce and between industry and supply were coordinated. Due to changes in market, high and medium-grade cigarettes produced by the Taiyuan Cigarette Plant sold slowly this year. The plant formerly planned to increase its production but commercial departments only purchased them in small quantity. After learning what had happened, leading comrades of the provincial CCP committee and the provincial government discussed with responsible members of the plant and asked them to produce easily marketable cigarettes in accordance with the needs of market. At the same time, they discussed with the commercial departments and decided that the commercial departments should purchase 90 percent of the cigarettes produced by the Taiyuan Cigarette Plant and the remaining 10 percent is to be sold by the plant itself. The varieties and grades of these cigarettes were to be fixed at proper proportions. Thus, a long-standing problem was solved. The provincial supplies bureau was in bad need of 5,000 tons of thin iron sheets and was not able to get them. While responsible members of this bureau were handling official business on the spot at the Taiyuan Steel Works, they were helped by leading comrades of the provincial CCP committee and the provincial government who acted as go-betweens in solving this problem. At last, the Taiyuan Steel Works voluntarily decided to produce the iron sheets in order to meet this demand of the provincial supplies bureau, although not much profit would be obtained from producing them.

While leading comrades of the provincial CCP committee and the provincial government were handling official affairs on the spot, they were not able to solve at once 23 problems put forth by the enterprises but they noted them all down, arranged them in proper order on a list, made clear which departments should be responsible for solving them and instructed these departments to solve them within a specified time.

PROVINCIAL DIRECTIVE ON SPRING FARMING ISSUED

Hangzhou ZHEJIANG RIBAO in Chinese 14 Mar 82 p 1

[Article: "Zhejiang Provincial CCP Committee and Zhejiang Provincial People's Government Directive on Doing a Conscientious Job of Spring Farming and Production"]

[Text] The busy season of spring farming will soon be here, and in order that no time will be lost in doing a good job of spring farming for an all-around bumper harvest from agriculture this year, the following directive has been issued:

1. All Levels of the CCP Committee and Government Should Attach Extreme Importance to Strengthening Leadership of Spring Farming and Production

Since the 3rd Plenary Session of the 11th Party Central Committee, heartening changes have taken place in the province's rural economy, and the situation has developed in an encouraging way. However, it should be realized that numerous problems still exist in the province's agricultural work. During the past few years, grain, cotton, hog and vegetable production has not been very ideal as a result of both natural disasters and problems with leadership. From the province to the prefectures and the counties, there has been a laxness in leadership. Cadres in some leadership organizations have gone into rural villages less, and in some communes and brigades grassroots cadres have not devoted great attention to agriculture. A look at the present situation shows that the energies of leaders in numerous places have yet to be concentrated on spring farming and production. Unless this situation is rapidly changed, the good situation in agriculture that has appeared will be hard to maintain and develop. Leaders at all levels must deeply realize the importance and urgency of the development of agriculture, and be extremely determined to expend maximum effort in diligent strengthening of the leadership of agriculture.

A good job in spring farming and production is the first battle in winning a bumper harvest in agriculture for the entire year. All levels of CCP committees and government should take spring farming and production in hand as the central task of the moment in rural villages. Leaders at all levels in the province, prefectures, counties, districts and communes should change their work style, cut down on the number of meetings they hold, go down into rural villages and concentrate their energies on attention to agriculture. In the period from now until May, leadership comrades in charge of prefectures, municipalities and counties should take the lead in going to the front lines of agriculture to investigate and study, to giving painstaking guidance, and to helping communes and brigades perfect agricultural production responsibility systems and do a solid job of spring farming and preparations for farming. In addition, all levels of leadership organizations should organize a group of cadres to go into the countryside to help the grassroots solve some real problems. Work situations following visits by leadership cadres from units in prefectural, municipal, county and provincial organizations are to be reported back to the Provincial CCP Committee and the people's government.

2. Propagandize with Great Fanfare Implementation of Central Committee Documents on Rural Work Problems, and Stabilize and Perfect Agricultural Production Responsibility Systems

The Central Committee documents on rural work problems summarize the practical experience of rural work during the past several years. They are a powerful weapon for continuing and developing a series of rural programs and policies since the 3rd Plenary Session of the 11th Party Central Committee, and for unifying cadre and mass thinking about production responsibility systems. The most fundamental need in strengthening leadership of agriculture and doing a good job of spring farming and farming preparation work is good propagandization and good implementation of the Central Committee documents on rural work problems.

Right after the lunar new year, many county and municipal communes used the Central Committee documents on rural work problems as basic teaching materials in combination with local realities for the training of brigade and production team cadres, which unified cadre perceptions of the situation, improved their consciousness about carrying out the programs and policies that have ensued from the 3rd Plenary Session of the 11th Party Central Committee, clarified the guiding mentality for institution of production responsibility systems and development of agriculture, clarified grassroots cadre responsibilities following establishment of responsibility systems, and encouraged a spirit of dare to do and dare to care, which have won very good results. However, a certain number of counties and communes have not aroused serious attention to these tasks and have not conscientiously taken them in hand. They must take them firmly in hand to remedy the situation. In addition, places without production team heads and those that have not instituted cadre remuneration should quickly elect production team heads and institute equitable remuneration for cadres.

All kinds of propaganda tools should be applied and all forms of propaganda adopted for the propagandization with great fanfare of the Central Committee documents on rural work problems so that the farflung cadres and masses will understand that China's agriculture must hue to the road of socialist collectivization, that ownership of the means of production, such as land, will not change for a long period of time, and that the collective economy's establishment of production responsibility systems will also not change for a long time. It is to be clearly propagandized that the period of large-scale changes in the production responsibility system lies in the past, and that existing responsibility systems, no matter their form, so long as most of the people are satisfied with them and they advance production, should be consolidated and a good job done to perfect them as a means of helping eliminate fears on the part of some that they will be changed, and mistaken suppositions that assignment to peasant households of full responsibility for task completion is the sole form of responsibility system. It is necessary to state clearly and with full assurance that the goal in instituting responsibility systems is the consolidation and development of the collective economy rather than not wanting a collective economy. Peasant household assumption of full responsibility for task completion does not mean that dividing up the fields for independent working is to be permitted. No matter the form of responsibility system, it must adhere to both making the most of the superiority of unified collective operation and arouse the enthusiasm of individual commune members to achieve both centralized management and contracting, that which lends itself to centralized management being managed in a centralized way, and that which lends itself to contracting being contracted. Production projects requiring centralized administration and management, in particular, should be under centralized control, while production tasks that lend themselves to decentralized work by individuals should be contracted out to individual workers or households. Production tasks requiring labor cooperation should be contracted to groups. Where difficulties in production exist in farming by individual households, cooperative efforts should be organized. An unequivocal attitude must be adopted and resolute correction done in cases where collective property, public accumulations, and tracts of mountain forests, mulberry groves, tea plantations or fruit orchards have been divided up.

In perfecting responsibility systems, attention should be directed to representative examples, using experiences gained at key points to promote work in all areas, adapting general methods to local situations, and giving tailored guidance. Production teams that practice various forms of responsibility systems linked to output should sign contract agreements in advance of the very busy season of spring farming. They should particularly do a good job of perfecting systems of responsibility that fix output quotas or assign full responsibility for task completion to individual peasant households to solve the problem of need for centralized management and mutual help and cooperation in production. Production teams practicing the fixing of output quotas or assignment of full responsibility for task completion to groups of households are to solve the problem of unified coordination, and study improvements in methods for calculating remuneration within teams. Production teams practicing fixed quota work contracting should also give serious attention to ways of upgrading and improving the system. Strict attention and implementation should be given to responsibility systems for industrial sideline occupations, for mountain forests and for economic crops. In addition, policies pertaining to farming, industry and sideline occupations should be handled well.

3. Enhancement of State Plan Guidance and Guaranteeing the Grain Crop Growing Area

In developing agricultural production, the planned economy must be foremost, market regulation supplementary. Following institution of various forms of production responsibility systems, agricultural production must continue to be carried out under guidance of state plans. There can be no growing of whatever one likes. In carrying out crop planting plans, many places are now giving attention to all-around planning that takes into account concern for all, and making equitable arrangements, the grain growing area being increased over last year. However, in many places cadre conception of state plans is weak, and a tendency toward liberalization exists in arranging crop growing areas as they take it upon themselves to pare down the grain growing area. This problem must arouse the serious attention of all levels of CCP committees and government.

It must be pointed out that ours is a province with a large population relative to available land in which the grain fields per capita average only 0.5 mu. Furthermore, population is increasing year by year, and needs for grain are steadily increasing from every quarter. During the past 2 years, reduction has occurred in the grain growing area. The people regard food as paradise, and eating is a matter of supreme importance. Unless we are ruthless about increasing grain production, development of economic diversification will be impaired; the overall national economic situation will be impaired; and even social stability may be impaired. We positively cannot have a happy-go-lucky attitude about this.

If grain production is to steadily increase, a certain growing area has to be guaranteed. The Provincial CCP Committee and the Provincial People's Government require all jurisdictions to maintain their grain growing area this year at the 1980 level, and those who have taken it upon themselves to reduce the area are to resolutely augment it. In implementing this year's agricultural production plans, they must repeatedly educate rural grassroots cadre and commune members to an all-around understanding of the program of "positively no slackening in grain production while actively developing economic diversification," concern for the situation as a whole, conscious obedience to state plans, and a guaranteed grain growing area. Furthermore, they must include these requirements in contractual agreements, and put them into effect in production teams, groups and households. Should contracting units and individuals take it upon themselves to reduce the grain growing area, all levels of the people's government should interfere administratively as required.

Commodity grain growing areas should regard even more seriously development of grain production. The should, on the basis of their own capabilities, adopt some effective economic measures to encourage production teams and commune members to grow more grain, increase grain output and provide more commodity grain to make new contributions to the country.

While giving attention to grain production, all jurisdictions should make full use of mountainlands, hills, coastal beaches and lakes for active development of economic diversification, steadily opening new fields of production.

4. Active Promotion of Agricultural Science and Technology, and Conscientious Implementation of Various Measures to Increase Output

Throughout the province, the farflung rural villages are starting a new upsurge of studying and using science. All levels of leadership should take account of this new situation and take full advantage of agricultural scientific and technical personnel at all levels, actively organize mass study of science and technology, and steadily upgrade the level of scientific farming. Right now the need is to emphasize attention to the following tasks for spring farming and production.

1. Intensification of cultivation and care of spring-flowering crops. This year's growth of spring-flowering crops has been rather poor, and there has also been a lot of rain recently requiring the digging of drainage ditches, proper fertilization, increase in prevention and control of cereal scab of wheat, barley and naked barley, in an effort to do everything possible to win a bumper harvest of spring grain.

2. Attention to spring sowing and seedling propagation. Crop patterns, the matching of crop varieties, methods of seedling propagation, and other measures for increasing yields are to be made the responsibility of teams and households. Places practicing the fixing of output or the fixing of full responsibility for task completion on individual households are to use either production team-controlled methods or voluntary association of commune members in stimulation of sprouting and planting, conscientiously fostering growth of seedlings.

3. Good use of material resources, such as fertilizer, seeds, farm implements and plow oxen. Advantage should be taken of the time before transplantation of the early rice seedlings to arouse the masses to grow grass and duckweed, to handle well policies on accumulation and contribution of fertilizer, and to increase accumulations of all kinds of miscellaneous fertilizers. There should be an all-around good job done of inspecting seeds, sunning them, selecting them and redistributing surpluses to areas of shortage. Early preparations should be made against a general shortage of seeds for the late crop. Seed production for hybrid rice should be planned in a centralized way, arrangements made and work started early. Urgent attention should also be given to farm tools, farm machines, plow oxen and material preparations of all kinds. In addition, it is necessary to buttress water conservancy project maintenance and management to assure water for use in agriculture.

All levels of leadership are to organize the strength of agricultural technology promotion units and scientific research units to zero in on the weak links in agricultural production in different areas, study ways to increase output, and help the masses solve problems in technology. The agricultural technology promotion network should be perfected, and a good job done in running commune agricultural science stations to take full advantage of their role. Various means, such as the running of technical training courses, on-site demonstrations, and making the rounds to give instruction, should be used to extend various effective measures for increasing outputs.

5. All Trades and Industries Are to Serve Agriculture, Actively Taking the Initiative to Assist Spring Farming and Production

Building of a solid agricultural foundation requires mobilization of forces everywhere to assist agriculture. Trades and industries may not regard service to agriculture as an added burden, but should regard it as a matter in which they have a stake. In giving help to agriculture, they should not consider only their own profits and losses and their own gain, but should be concerned about the concerns of agriculture, and think the thoughts of agriculture. Whatever agriculture urgently requires should be done whether or not there is any profit to be made. Even if losses ensue, it should be done; one cannot do only things that make money.

In order to support spring farming and production before it is too late, agricultural, industrial, scientific and technical, planning, materials, commercial, supply and marketing, transportation, and banking units should act on the basis of the new situation following establishment in rural villages of production responsibility system to formulate plans to help spring farming and production. They should prepare for and carry out promptly solutions to problems such as supply of materials, technical guidance, farm machinery maintenance and repair, providing energy, and issuance of farm credit to make a contribution to support of agricultural production.

TITLE: "Research on Axial-flow Threshing Cylinder"

SOURCE: Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 1, 1982 pp 55-72

TEXT OF ENGLISH ABSTRACT: In 1978 we built a large testing bed for axial-flow threshing cylinders, which were changeable for three types of cylinders, four concave types and five types of cylinder covers. Comparative tests can be made on seven different arrangements of the above-mentioned parts. During 1979-1980, we conducted 120 tests with this bed on threshing wheat, soybeans and maize.

Our conclusions are as follows:
1. For the seven arrangements of the working parts, the feeding capacities can all reach 6 kg/sec, loss percentage less than 1 percent, broken seed percentage of soybeans 0.5 ~ 1 percent, of maize 3 percent. Among them, the arrangement of spike tooth-vane type cylinders with three-grates type concave gave the strongest separating capacity and the best adaptability of seed moisture content, but it consumed more power. The arrangement of raspbar-vane type cylinders and three-grates type concave gave the best comprehensive results, but was less adaptable with seed

[Continuation of NONGYE JIXIE XUEBAO No 1, 1982 pp 55-72]

moisture content.
2. In the tests of all arrangements, the percentage of foreign substances in the threshed products was rather high when threshing dry wheat and soybeans, less when threshing wet wheat, and minimum when threshing maize.

I. GENERAL INFORMATION

STATE COUNCIL DIRECTIVE ON GRAIN PROCUREMENT, SALES ISSUED

Beijing ZHONGGUO CAIMAO in Chinese 20 Mar 82 p 1

[Article: "State Council Decides Sole Responsibility Work Contracting for Grain Procurement, Marketing, and Allocation Guaranteed Unchanged For Three Years Beginning From This Year's Grain Year"]

[Text] In order to meet the new circumstances in national economic development and to carry out the program of "positively no slackening of grain production while actively developing economic diversification," the State Council has decided that beginning from 1 April this year, that is the beginning of the 1982 grain year, that except for Tibet and Xinjiang, all provinces, municipalities, and autonomous regions will institute sole responsibility work contracting for grain procurement, marketing and allocation, guaranteed not to change for 3 years.

The State Council approved management method of sole responsibility work contracting for grain procurement, marketing and allocation guaranteed for a period of 3 years stipulated that the agreed upon fixing of all sole responsibility grain figures is to be done by refering to actual figures for the past several years, with future changes in development of grain production, procurement, and marketing taken into consideration. Sole responsibility figures for marketing include both nonagricultural and agricultural marketing as well as grain for special use expended by the central government. Inbound grain transfer sole responsibility figures include normal allocation and grain for special use expended by the central government, and outbound grain transfer sole responsibility figures are outbound transfer figures minus special use grain, and determination of quantities of principle kinds of grain inbound and outbound. After all the sole responsibility figures have been determined, they will remain unchanged for the 3 year period from 1982 to 1984.

This method provides, inter alia, that in order to meet the new circumstances in the collective agricultural economy of instituting production responsibility systems, the state may institute sole responsibility contracting for excess grain procurement by production teams guaranteed for a period of 3 years. After production teams, groups, and households have fulfilled their excess procurement tasks, they have the right to dispose of excess grain as they see fit. Production teams growing cotton, sugar crops, and vegetables, or engaged in fishing, salt making, forestry, or animal husbandry under guidance of the state plan, and those selling products to the state in accordance with the plan that are grain deficient year after year may institute sole responsibility work contracting for grain marketing guaranteed for a period of 3 years.

This method also stipualtes that once the state sets sole responsibility work contracting figures for grain procurement, marketing, and allocation, as a rule no readjustments will be made. Within the period of sole responsibility work contracting, when provinces, municipalities, and autonomous regions purchase more grain that they sell, it will be the responsibility of localities to store it as reserves from bumper years against lean years. If because of natural disasters or for some other reason new grain shortages occur, locales should take action themselves to solve the problem. In major disaster years when the central government is required to transfer grain to solve the problem, localities will subsequently have to pay it back. After all jurisdictions have fulfilled state excess grain procurement tasks, they may enter into negotiated purchases and negotiated sales of grain to move grain from surplus areas to shortage areas so as to enliven the markets, to even out grain prices, and to make negotiated pruchases a supplementary channel by which the state can control grain sources. Following sole responsibility work contracting for grain, all jurisdictions must conscientiously implement pertinent grain programs and policies formulated by the State Council.

COMPOUND LIVESTOCK FEED INDUSTRY DEVELOPMENT EXAMINED

Beijing RENMIN RIBAO in Chinese 19 April 1982 p 2

[Article by newspaper commentator: "Give Serious Attention to Development of China's Livestock Feed Industry"]

[Text] During the past few years, the livestock feed industry has developed fairly rapidly. The country has built 358 compound (mixed) livestock feed processing plants with a year-round output of more than 2,000 tons, and another 100-odd plants are in process of construction. Once construction of these plants has been completed, compound feed total output capacity will reach more than 2 million tons. Nevertheless, this is only about 4 percent of the country's total consumption of livestock feed, and is far from being able to satisfy the needs of animal husbandry industry production. Consequently, how to further develop the country's livestock feed industry should arouse the serious attention of leaders concerned.

Currently some comrades lack an accurate perception about development of the livestock feed industry. For example, some people suppose that "the problem of adequate grain production has not been solved yet, so it will be difficult to provide for livestock feeds," or "why be so fussy about livestock and poultry feed?" Such views are not well thought out. It is precisely because ours is a country with a large population relative to available land in which average grain levels are relatively low that compound livestock feeds are necessary in order to conserve grain. A comparison of the compound feeds that the country produces now with ordinary livestock feeds shows that when fattening hogs, the feeding time can be reduced by 2 to 3 months for a drop of about 20 percent in feeding costs. Its economic value is extremely clear.

One also hears that "compound livestock feed requirements are high, and China's livestock resources are inadequate to meet them." Certainly China's livestock feed resources are insufficient and quality is not high. However, one should also realize that many of the country's resources have yet to be used in a fully sensible way, and that even waste exists. For example, the cake residue from cotton and rape seeds has a 30 to 40 percent crude protein content. Each kilogram contains 3,000 digestible calories of heat, making them a fine plant protein livestock feed. Annually about 7 billion jin of such seed cake is largely used directly for fertilizer. Were it used as livestock feed first and later as fertilizer, or if the cake were added to a proper amount of grain and bran for feeding hogs, not only could grain be saved, but the effectiveness as fertilizer of the hog dung and hog urine would be much higher than that of the cake alone. Were half of the cottonseed and rapeseed cake produced annually in the country used for livestock feed, pork production could be increased by more than 600 million jin. In addition, some of the leftovers from the food and aquatic products industries as well as powdered silkworm chyrsalis also make fine sources of livestock feed. If only we would use them well, the problem of livestock feed sources could be gradually solved, and the livestock industry now abuilding would have great prospects.

Naturally this is not to say that there are no difficulties in development of the livestock feed industry. For example, financial and material resources are insufficient, and experience and technical strength is lacking. Therefore, how to develop a livestock feed industry with a Chinese character is a topic that merits our study. In this regard, some advanced areas have provided us fairly good experiences. On the basis of their own circumstances, Changzhou, Wuxi, and Suzhou in Jiangsu Province have made full use of existing enterprises to rebuild their livestock feed processing plants, receiving economic benefits in little investment of funds for quick results. The experiences of these areas show that the building of livestock feed processing plants requires proceeding on the basis of China's circumstances, acting according to capabilities, and being concerned about economic benefits. Naturally, it is also necessary to work from a universal basis to give attention to improving work. For example, in places developing livestock feed industries that have fairly good size, funds, and technical conditions to begin with, attention should be placed on improving technological equipment, on gradually operating a livestock feed additive industry, and an enriched livestock feed processing industry so as to increase the varieties of livestock feeds and improve livestock feed quality. You can believe that with further readjustment of the national economy, a new situation of rapid development will inevitably develop in China's livestock feed industry.

REPLACEMENT FOR MERCURY AND ARSENIC PESTICIDES REPORTED

Shanghai JIEFANG RIBAO in Chinese 15 Apr 82 p 2

[Article: "Particularly Effective New Pesticide To Prevent Cotton Seedling Root Disease and Wheat Smut. Toxicity Less Than One-Thousandth That of Former Pesticides"]

[Text] There is good news for peasants. The formerly difficult to control damping off and anthracanose of cotton, cotton seedling root disease, and wheat smut now have particularly effective new pesticides--"Banzhongling" and "Banzhongshuang." These new pesticides were successfully developed by the Shanghai Pesticide Institute. Recently, following approval by units of the Chinese Academy of Agricultural Sciences organized by the Ministry of Agriculture, they went into large-scale production.

Cotton seedling root disease and wheat smut are two of the 14 main agricultural diseases in China that cause extreme damage to the growth of cotton and wheat, frequently occasioning severe declines in output. Because of a halt to the use of "Ceresan" [ethyl mercuric chloride] and "Sanlisan," pesticides in which seeds were mixed, but which contained mercury that polluted the environment, and because of limitations on use of "Daojiaoqing" pesticide, which contains arsenic, in some places when cotton was planted only untreated seeds went into the fields, and cotton seedling root disease has made a general comback in all cotton growing areas. In order to solve this problem, following many years of research, the Municipal Pesticide Institute finally succeeded. Its toxicity is less than one-thousandth that of pesticides formerly used. Experiments conducted in cotton growing areas of Hubei show 65.8 percent effectiveness in the prevention and control of cotton seedling disease, and a maximum effectiveness of 85.5 percent. Experiments conducted in cotton growing regions of Heilongjiang Province show a better than 85 percent effectiveness in prevention and control of wheat smut, vastly higher than pesticides containing mercury or arsenic.

PURPOSES, PROCEDURES FOR LOAN ISSUANCE OUTLINED

Beijing ZHONGGUO NONGMIN BAO in Chinese 25 Mar 82 p 2

[Article by Lu Jianxiang [6424 1696 4382]: "How to Improve Agricultural Loan Economic Benefits"]

[Text] In his report titled, "The Present Economic Situation and a Program For Future Economic Construction," Comrade Zhao Ziyang pointed out, "Using every available means to increase economic benefits in each of the fields of production, construction, and circulation is a central issue." Natural this is also a central issue in agricultural loan work, and is a standard for evaluating the quality of loan fund use. Economic benefits from loans are manifested in two ways. First is whether production by the unit or individual supported by the loan produces the economic benefits it should. Second is whether the loan can be recovered on time for steady acceleration of the circulation of funds. The two are interrelated, but the former is fundamental.

In 1981 economic benefits derived from agricultural loans improved nationally. However problems of continued lack of serious attention to economic benefits remained in some places. Some loans have not been used to support key projects for increasing commune and production brigade increases in production and income. Some loans have been used by speculators and profiteers, and not only did not play a role in development of production, but rather destroyed production. Still other loans were turned into loans to provide favors, being diverted to help people invite others to dinner or send gifts in a bad situation of extravagance and waste. Even loans used for relatively porper purposes did not bring the economic benefits they should have.

How can the economic benefits derived from agricultural loans be improved? First it is necessary to do a good job of investigation and study in issuing loans. Only when circumstances are clear can loans be approved and be good loans. First, it is necessary to investigate whether the borrowing unit or individual's activities are in accord with provisions of state plans, whether they are in accord with party and state programs and policies, and whether they are in accord with requirements for readjustment of the agricultural economy. Second is investigation of the borrowing unit or individual's operating situation, production capabilities, and technical level. Third is investigation of whether the items for which the loan is to be issued will make the most of local advantages, achieving large economic benefits and quick results from little investment, and whether production, supply, and marketing channels are unimpeded.

Fourth is the need to investigate whether the borrowing unit or individual's credit and loans have adequate material backing, and what are their capabilities for repayment of the loan. From a basis of understanding circumstances, and in accordance with loan policies, principles, and plans, factually determine the purpose for which the loan is to be used, the amount, how it will be used, and its length.

Secondly, banks and credit cooperatives must link their own economic benefit and the economic benefit of the borrowing unit or individual, making lending operations penetrate into the individual links of production, exchange, distribution, and consumption of the object for which the loan is used. Only after credit funds have been loaned out and the objective for which the credit was issued goes into production can new value be created. Therefore, banks and credit cooperatives must go into the areas of production and circulation and think about what producers think about, worry about what producers worry about, and help producers with their needs, doing a conscientiously good job of production. It is also necessary to fully apply the wideranging quality of financial operations to open production and marketing channels, combining unit or individual operations with society's needs. Additionally, credit funds are intermingled with the borrowing unit or individual's funds, and with funds from other sources. This requires that banks and credit cooperatives help those to whom loans have been made do a good job of financial management, make equitable use of funds, reduce labor expenses, and improve the labor productivity rate to gain fairly high economic benefits.

Third is active promotion of loan agreement systems and diligently carry out economic contract methods. Loan agreements protect the interests of both borrower and lender and assure on-time repayment of loan funds. They are important contracts enjoying protection of the law. They are major means by which banks and credit cooperatives manage and use funds. Therefore, it is necessary gradually to establish and perfect agreement systems. When both borrower and lender sign the agreement, they must obey the legal stipulations, and diligently carry out pertinent party and state programs and policies. They must carry out a program of the planned economy foremost, market regulation supplementary. They must abide by the principles of equality and mutual benefit, reaching unanimity through consultation, and payment at equal value. Agreements link loans to the individual links of production, exchange, and distribution to form an interdependent and mutually restrictive organic whole that together promotes development of production and circulation of funds.

Fourth is help to borrowing units to do a good job of distributing profits. The principle of the interests of the country, the collective, and individuals must be adhered to, borrowing units being helped to verify earnings, recover "outstanding debts," repay "debts outstanding," not make any false estimates, or rash distributions, on the one hand, and in accordance with national policy stipulations to deduct all taxes to be paid, accumulations to be withheld, various expenses, and honoring required distribtuions to commune members on the other. Only in this way can the collective economy be strengthened and the enthusiasm for production of commune members be aroused. Bank and credit cooperative recovery of loans on due dates will also be assured. If these four kinds of work are done well, economic benefits from agricultural loans will gradually increase, thereby promoting development of the rural economy.

PREVENTION OF WHEAT DISEASE ERYSIPHE GRAMINIS DC URGED

Disease Widespread

Beijing RENMIN RIBAO in Chinese 10 Apr 82 p 2

[Article: "Tightly Grasping the Prevention and Control of Erysiphe Graminis DC, at Present, Disease in Some of the Wheat Regions in the Middle and Lower Reaches of Changjiang and Henan and Shandong Has Already Occurred. It Is Hoped That Each Locality Can Grasp the Task of Organizing Prevention and Control Tightly To Assure a Bumper Harvest of Summer Food Grains"]

[Text] In recent years, Erysiphe graminis DC has gradually worsened in the nation's large wheat regions. It has become a serious threat to summer food grains production. Last year, in some of the wheat regions in the middle and lower reaches of Changhiang and the north, summer food grain production dropped by 10 to 30 percent because of Erysiphe graminis DC. At present, the disease has occurred commonly in Hubei. The rate of occurrence of the disease in seriously affected regions of wheat fields has reached 100 percent. It is estimated that by the middle 10 days of April, a peak occurrence of the disease will occur. The disease has also begun in many regions in Jiangsu. According to forecasts by forecasting stations in Wuxian, Jiangying, Xinghua, and Funing counties, this year is also a year of serious outbreak of the disease. The occurrence and the degree of damage will approach those of last year, but the period of peak occurrence will be 10 days later than last year. The occurrence of the disease in the suburban counties of Shanghai City and in Anhui is similar to that in Jiangsu. The occurrence of the disease in most regions in Zhejiang is medium to slightly severe, although less severe than last year, but still more severe than other years. Occurrence of the disease in Hunan and Sichuan is not balanced. For example, the disease is more severe in Cili, Shaodong, Leshan, Chongqing, Rongxian counties and Rongxian city while the disease is slight in regions where spring drought has occurred and where water and fertility conditions are poor. The occurrence of disease in the highly fertile and highly irrigated wheat regions in the Huanghe River Valley in Henan and Shandong will also be medium or medium to slightly severe.

Because most of the wheat varieties cultivated at the various localities at present are not resistant to the disease, the major outbreak of Erysiphe graminis DC in the wheat regions last year has accumulated a large amount of bacterial sources this year. Each locality reported that this year, the application of nitrogen fertilizers was generally too much and too late. These all provided conditions for the spread of the disease. According to meteorological reports, some parts of the middle and lower reaches of Changjiang and Henan and Shandong had more rain. The temperature was slightly lower or approached that of normal years. These are favorable to the occurrence of the disease. It is hoped that each locality strengthens field surveys, combines local weather forecasts, does not lose the opportunity to organize prevention and control efforts to control the spread of the disease and to assure a bumper harvest of summer food grains.

Characteristics of Disease

Beijing RENMIN RIBAO in Chinese 10 Apr 82 p 2

[Article by Geng Bingjin [5105 4426 2516] of the General Forecasting Station of Agricultural Diseases and Insect Pests of the Ministry of Agriculture: "Erysiphe Graminis DC"]

[Text] Erysiphe graminis DC is a fungus disease. The leaves, the leaf sheath, the glume of spikes and the stem can all become infected by the pathogenic bacteria. At the beginning stage of the disease, small and light yellow spots first appear on the leaves. Then they expand into circular or oval diseased spots. White powder composed of hypha and separately growing spores occur on the diseased spots. During the late period of the disease, the diseased spots become greyish brown. As the disease develop, the green color of the leaves gradually fades and becomes yellow until the leaves wilt.

Erysiphe graminis DC selects its host strictly. Its spores are propagated by air currents. It most easily causes infection and spreads under a temperature of 12 to 18°C and when the humidity is saturated. In spring, the temperature is slightly higher. During the heading and flowering periods of wheat and barley, the weather is continuously overcast, sunshine is deficient, and humidity is too high. If drainage in the field is poor, and if too much nitrogen fertilizer has been applied, the disease can occur more easily.

Method of prevention and control: 1) select disease resistant superior varieties; 2) plant rationally densely and apply fertilizers so that nitrogen, phosphorus and potassium are used in balance, appropriately increase the application of phosphorus and potassium fertilizers, pay attention to cleaning the furrows and drain the water; 3) for prevention and control by chemicals, a lime and sulfur compound, carbendzxol, Tuzet, thiophanate can be used.

BRIEFS

HIGH LYSINE HYBRID CORN--Corn expert Li Jingxiong [2621 4544 7160] of the Crop Breeding and Culturing Institute of the Chinese Academy of Agricultural Sciences has bred China's first group of high lysine corn hybrid varieties, "Zhongdan 201," "Zhongdan 202," "Zhongdan 203," and "Zhongdan 204." Test results obtained during the past 2 years from more than 30 different sites have shown yields per unit of area approximating those of the presently widely grown fine hybrid variety, "Zhongdan No 2." Yields are generally around 800 jin per mu and maximum yields are more than 1,000 jin. These varieties are resistant to large and small leaf spot. [Text] [Lanzhou GANSU RIBAO in Chinese 22 Mar 82 p 3] 9432

IMPROVED SHEEP RAISING TECHNIQUES--Promotion of China's sheep improvement techniques has been going on for 30 years. Beginning with experiments in the period immediately following founding of the People's Republic, it went through the importation from abroad of fine varieties, use of artificial insemination techniques, development of improved hybrids, and on to the breeding of new breeds. At one time improved fine wool and semi-fine wool sheep numbered fewer than 10,000 head, but by the end of 1980 this number had grown to 36 million head or 35 percent of the total number of sheep in China. Prior to 1971, 80 percent of the wool used by the textile industry came from imports, but now 80 percent is domestically produced wool. In terms of economic benefits, a single improved breed fine wool sheep averages 3.5 kilograms of wool. Income from wool production alone is 14 yuan more than from indigenous sheep breeds. The 36 million head of improved sheep have increased output value by a total of more than 500 million yuan. In addition, they have increased mutton output by an annual more than 300,000 tons, with a value of more than 45 million yuan. Xinjiang Province, the first area in the country to begin production of fine wool sheep breeds, "Xinjiang combination wool and meat fine wool sheep," has promoted a large number of fine breed sheep everywhere and has played an important role in China's sheep improvement work. CSO: 4007/384

IMPROVEMENT SOUGHT IN EARLY RICE YIELDS

Fuzhou FUJIAN RIBAO in Chinese 24 Mar 82 p 1

[Article by Zhang Yonghe [1728 3057 0735], Longyan Correspondent Station: "Devote Efforts To Increasing Grain Yields Per Unit of Area. Longyan Prefecture Taps Potential To Do a Good Job of Scientific Farming"]

[Text] Proceeding from a foundation of setting the area to be planted to early rice, Longyan Prefecture leadership organizations have gone on to propose a main attack on yields per unit of area and the use of every available means to win a bumper harvest from the early crop.

Following investigation and study, the Longyan Prefecture CCP Committee and government administrative offices acknowledged Longyan Prefecture's consecutive increases in output during the past several years. Nevertheless, the prefecture's potential for increased output is still very great. A look at the prefecture's 2.08 million mu of grainland shows yields of double crop early rice to have been as high as 1,600 jin and as low as slightly more than 300 jin for an average of 499 jin. For intermediate rice, yields per unit of area were as high as slightly more than 1,500 jin and as low as slightly more than only 200 jin for an average of 542 jin. For double crop late rice, maximum yields were 1,500 jin per mu and minimum yields were 200 jin per mu for an average of 442 jin per mu. The differences between highs and lows have been very great. Were the prefecture's early rice yields per unit of area to increase to 800 jin, an increased output of more than 400 million jin would result from this increase alone.

How can grain yields per unit of area be made to rise? The Longyan Prefecture CCP Committee and government administrative offices have proposed, first of all, an adaptation of general methods to specific situations, and equitable readjustment of agricultural crop patterns, all places that lend themselves to the growing of double crops of rice persevering in the growing of double crops of rice. However, in places where the frost-free period is short and outputs from the growing of double crops of rice inconsistent, commune members should be encouraged to grow one crop of rice and one crop of miscellaneous other grains. In this way, consistently high grain yields can be assured and the growing of economic crops expanded to achieve development of both grain and economic crops. In another realm, commune members should also be encouraged to farm responsibility fields, make full use of the ground and of empty spaces for sensible amounts of intercropping, and arranging things flexibly.

Second, the level of scientific farming should be increased, key agricultural science and technology measures taken firmly in hand with vigorous promotion of high yield, strongly disease resistant varieties of early rice. For double crop rice, it is necessary diligently to summarize the lessons of many years' experiences of early rice sustaining damage from "May cold," for scientific planning of sowing and planting time. Special attention should be focused on the main reasons why rice yields per unit of area are not high, namely few effective panicles, a low heading rate, a lot fruiting rate, and low per thousand grain weight. Reasonably close planting should be done to increase the number of effective panicles. In view of the situation throughout the prefecture of imbalanced fertilization with nitrogenous, phosphate, and potash, cutbacks should be made in the amount of nitrogenous fertilizer used while use of phosphate, potash and organic fertilizer should be increased, the organic fertilizer allowing cutbacks in the quantity of chemical fertilizer used. In addition, a diligent job should be done of monitoring, reporting, preventing, and controlling diseases and insect pests.

Third is strengthening of the building of an agricultural technical crops. A personal responsibility system should be established for agricultural technical cadres and rotational training of the existing 1,900 agricultural technical cadres should continue. Focus should go on helping the more than 60,000 science and technology households study scientific agricultural knowledge, the experiences of competing for first place in high yields of intermediate rice of Yongfu Commune in Zhangping County being promoted so that scientific farming levels everywhere in the prefecture levels everywhere in the prefecture will go up a notch, forming movement for increased grain yields centering on a major attack on per unit yields.

MAJOR EFFORT DECREED TO IMPROVE YIELDS FROM LOW-YIELD FIELDS

Fuzhou FUJIAN RIBAO in Chinese 24 Mar 82 p 1

[Article by Wu Wenkeng [0702 2429 6972], Jianyang Prefecture Communications and Liaison Station: "Direct the Main Attack Against Intermediate and Low Yield Fields. Jianyang Prefecture Takes Firm Grip on Key Points in Implementing This Year's Measures for Increased Yields, Taking in Hand 1.45 Million Mu of Intermediate and Low Yield Fields"]

[Text] Recently Jianyang Prefecture convened a conference for exchanges of experiences on agricultural science and technology at Chongan County. At this conference, the Prefecture CCP Committee proposed the following. The prefecture's grain production this year is to be on the basis of stabilizing the existing grain growing area, and the main direction of attack is to be changed to improvement in low yield fields, inasmuch as there are many low yield fields in the mountain areas of northern Fujian, to increase yields per unit of area. Delegates related to this decision on the part of the Prefecture CCP Committee the fact of last year's furious efforts on 1 million mu of intermediate and low yield single crop late rice fields, which increased output by 70 million jin. They acknowledged the direction of attack to be the right one and in accord with reality.

Jianyang Prefecture has 3 million mu of cultivated land and sows an area of 5.4 million mu [by double cropping part of the 3 million mu], 1.95 million mu with double crops of rice, and 1.05 million mu with a single crop of rice. In 1981 double rice crop yields averaged 473 jin per mu, 600,000 mu yielding less than 400 jin per mu. Double crop late rice yields averaged 479 jin per mu, 400,000 mu yielding less than 400 jin. Single crop late rice yields averaged 510 jin per mu, 450,000 mu yielding less than 450 jin per mu. Low yield fields thus amounted to 1.45 million mu. In view of these circumstances, the Prefecture CCP Committee regarded as not very high northern Fujian grain yields per unit of areas and believed potential to be very great. If only increases of 50 jin per mu could be realized from these intermediate and low yield fields, which account for one-fourth of the total, output could be increased by 72.5 million jin, three-fourths of the quota for increased output for the entire year.

The Prefecture CCP Committee proposed the following actions in the attack on intermediate and low yield fields:

1. Attention to propaganda and education work to correct an attitude that emphasizes high yield fields and slights low yield fields, emphasizes good fields and slights bad fields, and emphasizes fields close by one's dooryard while slighting ridged fields in distant mountains that exists among some cadres and masses. 2. Further summarization, perfection, and consolidation of agricultural production responsibility systems, diligent attention being given the making of contracts. These contracts may be guaranteed without change for 3 or 5 year periods so that peasants can do some long-range planning on improvement of low yield fields. 3. Energetic promotion of scientific farming. The main reasons for low yields from low yield fields in northern Fujian mountain areas are, first, natural disasters, foremost of which are "return of spring coldness," "May cold," "autumn cold," "high temperatures," and "June rains." Second is disease and insect pests, notably blast of rice. Third is seedlings just sitting without growing. In this regard, vigorous efforts should be made to increase combat against disasters, to guard against disease, and to do agricultural science and technical work. Fourth, all trades and industries should vigorously support agriculture, and vigorously improve low yield fields.

Right now all jurisdictions are in process of implementing the Prefecture CCP Committee's actions and arousing the masses to do a good job of spring farming and production.

IRRIGATION PROBLEMS RESULTING FROM DECENTRALIZATION DISCUSSED

Fuzhou FUJIAN RIBAO in Chinese 18 Mar 82 p 2

[Article by Reporters Lin Ben [2651 1149] and Yan Zhenyu [7346 2182 5148]: "Solution to the Problem of Farmland Irrigation Difficulties"]

[Text] In some counties and communes in Jinjiang Prefecture, spring drought has appeared during the past several days, and water is badly needed both for wheatfield irrigation, and for spring farming of the thawed fields, yet people rarely go to the reservoirs to request release of water. Could it be that there is no water in the reservoirs? No. Units concerned have explained that more than 300 million cubic meters of water are in storage in reservoirs of all kinds throughout the prefecture, and water is sufficient for spring farming. Then why has this abnormal situation occurred?

We conducted an investigation in Jinjiang Prefecture agricultural units where we learned it is mostly because following rural promotion of various forms of contract responsibility systems linked to output, a series of new circumstances and new problems have arisen in management and use of water, and these new circumstances and new problems have not yet been satisfactorily solved. They are mainly as follows.

First, the units using water have changed. Formerly it was production teams and villages that made collective requests to reservoirs for the release of water. They contracted for an amount of flow, fees being collected per cubic meter under unified management. Last year following institution of production responsibility systems, units requesting use of water changed from teams and villages to myriad households.

Second, the organization in charge of water has scattered. Formerly each irrigation zone established an irrigation zone representative assembly, which held regular meetings and studied farmland irrigation problems. A combination of specialized management and mass management was practiced in water conservancy and irrigation. In the irrigation zone, every production brigade had a chief of brigade water control, and every production team had personnel for water control who were responsible for brigade and production team requests for water, release of water, and collection of fees. After responsibility systems were put into effect, the commune, brigade, and masses control teams came to a standstill, and in many brigades and production teams in which the problem of their remuneration had not been solved, the personnel in charge of water control simply disappeared and no one was centrally responsible for requesting water, releasing water, or collecting fees.

Third is difficulties in asking for water and releasing water. Nowadays no one is in charge of silt removal from the ditches, so anyone who wants to request water frequently has to remove the silt himself. As a result, commune members who have contract fields "on the tail end of the water" back away from using water because they fear that because of the long ditches, much water will be consumed and they will have to spend a lot of money, in addition to which they will have to clean out the ditches. Commune members at the "head end of the water" like to wait until those "on the tail end of the water" ask for water. They then take the occasion to intercept the water or bail it out with buckets rather than ask for water themselves. In some places have appeared "strong ones" who won't ask for water, and "weak ones" who do not dare ask for water. When water is used, no one admits to owing for it, and when water is released no one looks after it, which has led to outbreaks of quarrels over water rights and the destruction of water conservancy facilities. Last year at Nan'anguanqiao Commune, because commune members at the "head end of the water" and at the "tail end of the water" took a wait-and-see attitude toward each other, much of the several tens of mu of crops parched to death creating a drop in output. Nowadays in some places where fields need water, the same thing happens.

Because leaders devoted considerable attention and adapted to the new rural situation of production responsibility systems, strengthened investigation and study, and adhered to the mass line at the Sizhou Reservoir in Huian County, the Houqiao Reservoir in Nan'an and at other places in this prefecture, water conservancy and irrigation problems were solved rather well. Now that the need for water for spring planting is extremely imminent, all levels of leadership must solve the following several problems.

1. Rapidly revive and reestablish the mass control corps for water conservancy. Production birgades and production teams are to revive and put in place personnel in charge of water, establishing centralized planning, centralized irrigation, and centralized settlement of accounts and payment of water fees by commune members using water to irrigate their fields. In units in which the collective economy is run fairly well, remuneration for water control personnel may be paid from the collective's "three monies," or from earnings of commune and brigade enterprises. In units in which the collective economy is fairly weak, discussions may be carried out with the masses to find some other means of providing allowances. Where conditions permit, irrigation zone representative assemblies may also be revived and hold regularly scheduled meetings to study irrigation zone irrigation problems, and to work out systems of responsibility or rural civil agreements to resolve fights over water rights. Specialized reservoir corps should also be strengthened, and specialized personnel motivated to develop the raising of fish, the growing of fruit and processing in reservoir areas as part of economic diversification to increase earnings to solve present difficulties in some reservoirs of "using water to support water."

2. The problem of clearing silt from ditches must be solved. In many places a system of contracting the clearing of silt from sections of ditches virtually does not exist. In some brigades or production teams, only when compelled by circumstances are some people called upon to clear the ditches, and more than 2 yuan per day in wages has to be paid before anyone is willing to do it. They

do not dare arouse commune members to contribute obligatory labor fearing increase in unreasonable burdens on the peasants. When we solicited the views of some comrades in prefecture agriculture departments, they felt that proper organization of peasants to do some obligatory labor in public welfare endeavors such as removing silt, looking after dikes, and protecting water conservancy facilities was permissible and could not be considered an unreasonable burden. Some suggested that it might be possible to revive the method used before the "cultural revolution," of centralized control by communes. In this way, removal of silt and requests for water could be dealt with promptly for the convenience of commune members. All locales can discuss this problem to find a way to solve it.

3. Need for change in method of collecting water fees. Judging from the experiences of some communes and brigades in Jinjiang Prefecture, a change to the collection of fees in cash would be well received by users. Of course, one can also proceed from realities to adopt some other method. For example, payment can be made first and accounts settled later, or tickets for water could be purchased with cash ahead of time and water provided in return for water tickets. Under special circumstances, water could be released into culverts or conduits at the time cash was paid. If these methods posed difficulties, water could be released and regular fees paid later on the basis of contracts, etc. Where conditions permit, communes and production brigades might also take control of the water with uniform payment of water fees.

4. Support and coordination required from every quarter. For example, the Shanmei Reservoir irrigation zone extends over three counties and one city, but a problem that is now encountered is that water is released only when they want to generate electricity. Sometimes farmlands urgently need water, but they will not start up the machinery to release water. Last year, for example, Huian encountered such a situation in combating drought, and the masses have a lot of complaints about it. They demand that water and electricity be closely coordinated, with overall arrangements made so that electricity can be generated to increase economic benefits, and irrigation of the fields can be assured to support agricultural production.

NEED FOR GRASSROOTS IDEOLOGICAL INDOCTRINATION UNDERSCORED

Fuzhou FUJIAN RIBAO in Chinese 5 Feb 82 p 2

[Article by Sanming Prefecture CCP Committee Secretary Deng Chao [6772 6389]: "Affirm the Rural Mainstream and Correctly Guide"]

[Excerpts] As a result of resolute implementation of the spirit of the Third Plenary Session of the 11th Party Central Committee and the steady elimination of "leftist" ideology, Sanming Prefecture's rural villages' total grain output for 1981 surpassed the all-time high; economic diversification increased tremendously; and commune and brigade enterprises continued to develop. The broad masses of peasants became even more enthusiastic about socialism and had full confidence in prospects for the four modernizations. Nevertheless, some new problems urgently in need of solution also appeared, foremost of which were the following: Some cadres and members of the masses mistakenly supposed that peasant household assumption of full responsibility for task completion meant "return to families of land and a division of the field for working individually," consequently dividing up the cultivated land and collective property on the basis of population. Some people did not want to assume any obligations or responsibilities whatsoever, and when it was time to sign contract agreements, they higgled and haggled or raised an unreasonable rumpus, refusing to sign or, having signed, refusing to implement. Some cadres and members of the masses mistakenly supposed that following peasant household assumption of full responsibility for task completion that "everything reverted to individuals for handling with no need for leaders," and they would not listen to proper guidance. Some production brigade and production team cadres did not dare work boldly; they cared only about their own individual production, and were unconcerned about the public welfare. Some state cadres even used the excuse of returning home to help their dependents a farm the land to absent themselves from their duty posts for long periods of time. In some places evil winds and noxious practices sprang up in smuggling, opportunism and profiteering, reckless felling of trees and denudation of forests, feudal superstitions, gathering together to gamble. and taking over good farmland for the building of houses. Some of these practices came into being under the leadership of grassroots organization leaders or with their tacit permission. The Prefecture CCP Committee felt that though these problems were confined to a minority of communes and brigades, and were problems of understanding for the most part, nevertheless, if allowed to spread, they would become unmanageable. In mid-November 1981, the Prefecture CCP Committee decided that following the harvest, concentrated indoctrination on socialism and patriotism would be given the peasants. Prefecture leadership comrades went to the countryside to propagandize, and CCP committees in counties (or municipalities) and communes ran pilot projects. Two months of experiences have shown that all levels of the party organization have had some new understandings about conducting regular indoctrination and providing correct guidance for the broad masses of peasants.

(1)

One must firmly believe that the broad peasant masses want to take the socialist path under the leadership of the party.

In our prefecture, more than 90 percent of all production teams practice either peasant household assumption of full responsibility for task completion or the fixing of output quotas based on households as forms of production responsibility systems. We have demonstrated as a result of much investigation that it is the fetters of egalitarianism, excessive burdens, and resort to coercion and commandism, which have endured without solution for many years, that the broad masses of peasants want to free themselves from, but they still strongly demand that the party give correct guidance and develop socialist agriculture. This is the mainstream in rural villages. This fundamental estimate can find fresh reflection in the following several matters.

One is that results of last year's struggle against disaster were even better than had formerly been estimated. During the first half of 1981, a "June freeze" such as has rarely ever taken place occurred in our prefecture, and quite a few communes and brigades also sustained torrential rains and floods. Of particular note was the worst outbreak of rice blast since Liberation. Large areas of early rice were devastated, and it continued to spread to double cropped late rice fields and single crop late rice fields. Faced with a situation of such serious hardships, no flights of peasants from famine occurred in rural areas. Under the guidance of the party organization at all levels, the broad masses of peasants prepared to combat disaster, and many moving, real-life incidents occurred. Early crop losses in the prefecture amounted to 200 million jin, but after arduous struggle, defeat was finally turned into victory, and a heartening achievement of an increased grain output of somewhat more than 30 million jin for the year as a whole was won by the prefecture.

Another is the establishment and perfection of agricultural responsibility systems that are more healthy than had been originally forecast. This is a large-scale transformation that affects a myriad of households, the development of which has been extraordinarily rapid, yet major public property such as forest trees, water conservancy, and plow oxen have not been destructively damaged. Statistics show that in 1981 the mountain areas burned in the prefecture declined by almost half over the previous year; reckless felling of trees and denudation has rapidly taken a turn for the better; and an increase has occurred in the number of the prefecture's plow oxen. Particularly heartening is that the building of collective economically diversified bases continues. Last year 200,000 mu of moso bamboo was restored throughout the prefecture. This was 2.8 times the originally planned 70,000 mu. The newly developed more than 40,000 mu mountain tea growing area also achieved the plan figure that had been set. In rural villages, an extremely small number of peasants thought of "liberalization" for a time, but repented very quickly after indoctrination.

Still another matter is procurement of agricultural products, which increased once we diligently turned our attention to it. By 23 December 1981, the prefecture had fulfilled its grain requisition purchase tasks, and throughout the prefecture appeared numerous households that sold more than 10,000 jin of grain. In Jianning County, after Li Guangdong's [2621 1684 2639] household had sold 40,000 jin of grain to the state, a tremendous upsurge of competition in contributions took place throughout the county, and households in the county that sold more than 10,000 jin of grain numbered 740. Formerly our prefecture's performance in the sale of live hogs was fairly poor, but once attention was directed to this following the autumn harvest, during the 2 months of November and December the state bought more than 50,000 head, which was 40 percent of the entire year's quota. Most counties including Jiangle, Taining, Mingqi, Jianning, and Ninghua overfulfilled their quotas. Throughout the prefecture, many individual peasant households sold the state three or more pigs.

(2)

It is necessary to boldly and assuredly propagandize the principle that for peasants to become rich, there can be no departure from socialism.

How can propagandizing the "four perseverances," "concern for the three" [the country, the collective and individuals], and the "two oppositions" be made easily understandable, vivid and concrete, achieve the purpose of stirring the minds of the peasants, and form social opinion? Throughout our prefecture, results obtained have been good from leadership comrades taking the lead in propadizing, who have used the methods of linking the propaganda to local realities and working along several lines at the same time. In concentrating experiences from everywhere, most important has been taking into account the following three matters: One is to take account of state support for agriculture. First the accounting for the prefecture and counties must be layed out. Since the Third Plenary Session of the 11th Party Central Committee in the 3-year period between 1979 and 1981, our prefecture's local financial organization has allocated a total of 32.68 million yuan for the support of rural construction, an average of 109 yuan per peasant household, and this has been related to the situation in individual communes and brigades.

The second is to take into account subsidies made by the state. Subsidies made by the state during 1981 for major losses in the prefecture for nitrogenous fertilizer, phosphate fertilizer, threshers, and diesel fuel have amounted to 7.48 million yuan, an average of 24 yuan per household. In addition there have been subsidies for rural electricity, rural salt, and rural pesticides. In propagandizing at individual places, talk was even more concrete on how the phosphate fertilizer brought in by the government cost between 160 and 170 yuan per ton, but was sold to the peasants for only 140 yuan; how each threshing machine cost 83 yuan, but was sold to peasants for somewhat more than 40 yuan, and how each ton of diesel fuel cost 310 yuan, but was sold to the peasants for 195 yuan, etc.

The third matter is to take into account the reduction in prices of industrial goods and the increase in price of agricultural products. In addition to figuring the total bill, it was demonstrated that as a result of increases in prices paid for agricultural products, the peasants in the prefecture had increased earnings of more than 50 million yuan last year as compared with 1978. Even more instructive was to proceed from local realities using representative commodities to make a comparative accounting.

(3)

It is necessary to strengthen grassroots organizations and ro rely on them to steadily imbue peasants with socialist ideology.

Implementation of all the party's programs and policies, fulfillment of various work tasks, and intensification of ideological and political work all require reliance on rural grassroots organizations. As a result of our prefecture's resistance to disasters to win bumper harvests last year, improvements in production responsibility systems, and fulfillment of various work tasks, the party cadre ranks at the grassroots levels of our prefecture have combat strength, but it must also be realized that the workstyle of a minority of party members and cadres is itself not proper. Numerous grassroots organizations are loose-knit and weak. How can rural grassroots organizations, including the party organization, political organizations, and mass groups be strengthened? The knowledge gained through experience by various places in our prefecture is as follows:

1. A popular saying goes: "One village looks at another; one household looks at another; but the masses look at the cadres." Use of the party's style to spur on the people's style is exactly what Central Committee leadership comrades have been talking about recently. For rural social practices to make a decisive turn for the better, the key lies in rectification of party style. Simultaneously with the launching of indoctrination in socialism and patriotism in rural villages, the Prefecture CCP Committee and each county (or municipal) CCP committee directed attention to several major economic cases to uncover problems involving violation of the law and confusion of discipline, which were handled strictly in accordance with party discipline and the laws of the land, with positively no leniency shown. Improper conduct of a routine nature on the part of rural commune members and grassroots level cadres was mostly corrected by those involved as a result of criticism and self-criticism as part of indoctrination.

2. Evil practices and noxious influences must be obliterated. Most recently, each county (or municipal) CCP committee and commune CCP committee selected key points and pilot projects to find out how to put a stop to use of cultivated land for the building of houses, the felling of trees and denudation of

forests, assembling for gambling, feudal superstition, opportunism and profiteering, and such evil influences and noxious practices. Experience in pilot projects shows that if the attitude of leaders is resolute, the masses are fully aroused, and a fair, reasonable and legal popular consensus is worked out on the basis of national policies and ordinances and the pooled wisdom of the masses, and if this is carried out impartially, people being treated equally and without discrimination, large problems that have endured for a long time can be solved.

3. Energetic commendation of the advanced. Most recently, the counties (or municipalities) of the prefecture have convened a series of agricultural front commendation meetings that have singled out for commendation a large number of production brigade and team leaders, good party branch secretaries, and such cadres from units large and small.

4. Equitable remuneration for grassroots cadres. At the Prefecture CCP Committee Rural Work Conference held last October, we established a system whereby production brigade cadres are to receive fixed allowances, rewards, and punishments. Following the autumn harvest, all counties (or municipalities) devoted much attention to implementation of this system. Statistics from the four counties of Jianning, Taining, Qingliu, and Ninghua show that annual allowances for production brigade mainstay cadres (largely party branch secretaries, production brigade chiefs, and for finance and grain, barefoot doctors and farm technicians) required a total of 810,000 yuan, which has been paid. At the same time production brigade groups were reorganized and systems of personal responsibility established. Now an overwhelming majority of production brigade groups have taken over the economic and administrative functions for which they are responsible.

SPRING PLANTING REPORTEDLY OFF TO GOOD START

Lanzhou GANSU RIBAO in Chinese 20 Mar 82 p 1

[Article: "Spring Planting Begins in One Place After Another in Gansu. This Year's Preparations For Plowing Fairly Solid; Both Cadres and Masses Strive to Win Good Harvest"]

[Text] Now that the period of the excited insects has passed [approximately 5 March] spring planting has begun in one place after another in Gansu Province. From the banks of the Bailong Jiang to the basin of the Shule He, and from the central region to the western corridor of the Huang He, the spirit of the masses of cadres and commune members has been aroused. They have begun early and acted quickly, and farming has been done solidly and painstakingly in the area already planted.

Statistics from units concerned show an area of more than 41 million mu in the province planned for the sowing of grain this year, 12 million mu of which is overwintering crops, which are now greening up; and 15 million mu of which is the fall ripening grain growing area, which is now being plowed. Right now myriad households are in process of laboring hard to complete the planting of 14 million mu of spring-sown summer ripening grain crops. This year's spring sowing is characterized in the following several ways: 1. Intensified planning of planting. In most places, commune members and production teams have already signed responsibility contracts or are now in process of signing them. 2. Last winter and this spring, the province had rather scant rain or snow and drought occurred in some places. However, before spring planting began, everywhere plowing and harrowing was done quite well. In Gaolan County, for example, 200,000 mu of sandy fields have been gone over three times. In Yuzhong County, the soil in 920,000 mu of the 1 million mu of fields for which planting has been planned has been turned once or twice. In riverland and irrigated areas, attention has been given to both irrigation and leveling of the fields. Recently some rain and snow has fallen, so the soil moisture situation everywhere is suitable for spring sowing. As a result of the increase in domestic livestock and poultry, both quantity and quality of farmyard manure is better than it has been for many years. All levels of supply and marketing units have promptly hauled to the countryside more than 273,500 tons of chemical fertilizer, which substantially satisfied needs for spring plowing and production. 4. In advance of planting this year, the enthusiasm of the broad masses of peasants for exchange of superior varieties was very high. In Linxia Zhou, for example, in addition to transfers from areas of surplus to areas of shortage by commune members in mountain and flatland areas, within communes and brigades, and between one household and another, through which an exchange of more than 1.5 million jin of superior variety seeds was made, the zhou and county seed companies also brought in 500,000 jin of superior varieties of wheat, soybean, and corn seeds from Jilin and Shaanxi provinces, and from Lintao. All counties in the province also took active measures to help the masses make timely exchanges. 5. Before spring planting began, all jurisdictions dilligently took in hand the repair and maintenance of large and small farm implements. Acting in accordance with the various rural responsibility systems that have been instituted, agricultural banks and credit cooperatives at all levels went into communes and brigades so as not to lag behind the farming season to issue 85.26 million yuan in agricultural loans. This solved difficulties for some commune members in buying farm implements and having insufficient funds for other preparations for farming, and vigorously assisted spring plowing and production.

By way of fighting a good battle in this year's spring farming and to strive to make agricultural production better than last year, provincial organizations made early transfers of 180 cadres who were led by the directors of 18 departments and formed into 38 investigative work units for dispatch everywhere in the province to help the grassroots start work. All prefectures, counties, and communes also strengthened leadership of spring planting and production. In the course of spring planting, many agricultural technical cadres worked with the masses on plans for scientific farming.

EFFORTS TO REMEDY SOME WATER CONSERVANCY PROBLEMS REVIEWED

Lanzhou GANSU RIBAO in Chinese 14 Mar 82 p 2

[Article by Yang Chongyi [2799 6850 0001]: "Heartening Achievements in Gansu's Water Conservancy Research Using Principally Applied Research Firmly Geared to Production"]

[Text] By firmly gearing to the needs of production and using most applied scientific research, Gansu Province water conservancy research has won heartening achievements. As of the end of the year, most prominent were the following: A concise zoning report was presented on the Huang He, the Chang Jiang, and internal waterways throughout the province; research on fluid control butterfly valves and corrosion-resistant and abrasion-resistant coatings for water pumps showed definite economic effectiveness; experiments had reached a certain stage of completion in the removal of turbidity from water stored in reservoirs, in preventing the heaving of water conduits, and with bitter water, some economic benefits having taken place. The ground water mainstay cadre observation network in the western part of the Huang He has been preliminarily built.

In the development of water conservancy endeavors, numerous real problems urgently in need of solution occurred to provide new topics for water conservancy research. Take the frost-upheaval of water conduits, for example. In the western corridor of the Huang He in Gansu Province, the climate is frigid and the soil freezes to a maximum depth of from 0.8 to 1.84 meters. Damage done through frost-upheaval to the brickwork beneath the irrigation conduits is substantial. Light damage has to be repaired annually, a great expenditure of manpower and material resources being necessary. Heavy damage impairs passage of water through the conduits, or the conduits have to be scrapped. In 1979 the provincial water conduit experimental research group to counter freezing began work on this problem, and after several years of on-site observations and experiments it won preliminary successes in mastering the mechanisms of frost-upheaval, of the relationship between frost-upheaval and the thickness of the cushioning layer, and of various forms of supporting brickwork and things to be on guard against. In its application to production, this saved the country funds, materials, and manpower.

Successful development of fluid control butterfly valves has been of crucial technical importance, both theoretically and from a practical standpoint, in solving problems with high life large volume flow, reverse pumping through long pipes by pumping stations, hydraulic boosting, and safe operation of crisis pumping stations for which the province conferred a citation third class for accomplishments in scientific research in 1980.

Experiments with removal of turbidity in reservoirs provided scientific experimental data for solving the province's problems in building reservoirs into which streams carrying large quantities of silt flow, and in the elimination of silt build-up. At the Dongxia Reservoir in Jingning County, where experimental research was conducted for 4 years, an accumulated total of more than 6 million cubic meters of silt was discharged from the reservoir, and more than 1.7 million cubic meters of ditch and reservoir capacity flushed out. This made possible a preliminary abundant sluicing from dwindling storage, no flooding of shorelands, and a balance between flushing and silting for many years to extend the life of the reservoir and achieve the objective of assuring irrigation while saving on construction investments.

The eight ground water observation tracts undertaken by the provincial Water Conservancy Department have begun to be built; a start has been made on dynamic analysis and resources appraisals; and the results of study of the three tracts at Wuwei, Xiaheqing, and Jinta have been applied to the zoning of water conservancy and readjustment of the distribution of pump wells begun locally to guide the build-up of production.

At the recently convened provincewide conference on water conservancy work, working from production realities in Gansu Province, water conservancy research workers layed out the research projects to be done. They resolutely mobilized all scientific and technical forces to strive, on the basis of realities in the building of production, to advance water conservancy research work in Gansu Province.

AOLUO RAPESEED GROWING AREA ENLARGED

Lanzhou GANSU RIBAO in Chinese 16 Mar 82 p 1

[Article by Li Duanchong [7812 4551 1813]: "Linxia Hui Autonomous Zhou Continues to Extend Growing of Aoluo Rape. Area of Zhou Planted This Year Enlarged To More Than 10,000 Mu"]

[Text] The Linxia Hui Autonomous Zhou has taken action to continue increases in the growing of Aoluo rape. Plans call for an expansion to 30,000 mu of this year's Aoluo rape growing area. This amounts to about 30 percent of the area sown to oil-bearing crops, and a more than 12,000 mu expansion over last year.

Aoluo rape is characterized by high yields and a high oil content. At the end of 1978, the zhou seed company introduced 3,000 jin of Aoluo rape from Qinghai Province. After 3 consecutive years of experiments and demonstration planting at numerous sites in areas of different kinds, yield increases vastly greater than those from local varieties were obtained. Last year the area to which the cultivation of Aoluo rape was extended in the zhou amounted to more than 17,800 mu, which was 19 percent of the total area sown to oil-bearing crops, but output amounted to 32 percent of the total oil-bearing crop output. Last year oil-bearing crop yields per unit of area in the zhou increased by 12 jin over the bumper harvest year of 1980, and total output increased by 1.82 million jin.

After several years of experimental plantings, Aoluo rape has "found a home" in the Linxia area. This year plans call for an expansion to 30,000 mu of the Aoluo rape growing area in Linxia zhou. This will amount to about 30 percent of the total area sown to oil-bearing crops.

INCREASED EARNINGS RESULTING FROM CHANGES IN CROP PATTERNS REPORTED

Lanzhou GANSU RIBAO in Chinese 28 Mar 82 p 2

[Article by Li Peiliang [2621 1014 0081], Secretary, Jianhu County CCP Committee, Jiangsu Province: "Production of Wealth to Bring About Prosperity Through Increased Grain Production"]

[Excerpts] How is it possible to steadily increase commune members' earnings while achieving steady increases in grain production? Lugou Commune in Jianhu County has answered this question. In 1981 this commune's earnings from industrial sideline occupations amounted to 8.6 percent of total earnings. This was eight percent lower than the average for the county as a whole, yet earnings distributions to commune members were the highest in the county, averaging 190 yuan per capita. What was the reason? In addition to improving soil fertility and perfecting the crop rotation system, they also readjusted the crop pattern for different varieties, expanding the wheat, glutinous rice and hybrid rice growing areas, thereby achieving increased output and increased earnings.

They realized as a result of experience that wheat will tolerate wetness to produce consistent yields, and that water-laced lowland areas lent themselves to increased growing of wheat. They, thereupon, expanded the wheat growing area while cutting back on the barley growing area. In the case of rice, they kept the hybrid rice growing area constant while expanding the glutinous rice growing area and continuing to grow conventional xian rice varieties. In 1981 the area planted to wheat was 60 percent of the area planted to wheat, barley and naked barley; hybrid rice accounted for 63 percent of the area planted to rice; and glutinous rice occupied 11 percent of the area planted to rice. They also mobilized commune members to grow wheat and glutinous rice on their private plots for self-sufficiency so that more of the wheat grown by the collective could be sold to the state. In that year alone, grain yields increased to 1,544 jin per unit of area, wheat and glutinous rice accounting for 52.4 percent of the total amount of grain sold, an amount almost double that of 1979.

The foregoing has discussed increases in output; now let us take a look at prices. In accordance with state procurement prices, wheat was purchased at 0.163 yuan per jin, which was 0.054 yuan higher than the price paid for barley. The price paid for procurement in excess of quota was 0.244 yuan, which was 0.081 yuan higher than for barley. The price paid for glutinous rice was 0.046 yuan per jin higher than for conventional xian rice, and the price paid for procurement in excess of quota was 0.08 yuan higher. When the two factors of output and price were taken together, this commune's 1981 earnings from the sale of grain increased by more than 180,000 yuan as compared with 1979, and average per capita income increased by 46 yuan. As the masses said, "A change in varieties, and income has grown by one-half."

In addition to the aforementioned increase in economic benefits, the equitable readjustment of the distribution of varieties was characterized in the following several ways:

First, it helped put in place state grain production plans. The masses desired greater material benefits, and equitable readjustment of the distribution of crop varieties made commune members realize that economic benefits derived from producing grain were in no way less than from the growing of economic crops such as cotton.

Second, it helped provide the state with commodity grain of good quality and high economic value. Wheat and glutinous rice are both commodities for which both state and popular demand is very great. When more of these commodities provided the state, the state can reduce imports of grain while at the same time satisfying the needs of the people's livelihood.

Third, both wheat and glutinous rice make fine raw materials for processing into foodstuffs. Greater production of these grains means development of the food processing industry to satisfy market demand and increase their economic value.

IMPORTANCE OF STURDY SEEDLINGS FOR BUMPER RICE HARVESTS STRESSED

Lanzhou GANSU RIBAO in Chinese 28 May 82 p 2

[Article by Ou Weizhong [2962 4850 0022] and Tao Ruhan [7118 3067 3352]: "Three Ways to Grow Sturdy Early Rice Seedlings"]

[Text] The vernal equinox has passed and spring has returned to the good earth. Early rice has already been sown in China's southern regions, and in the farflung rice growing areas of the Chang Jiang basin and the southwest, preparatory work for the growing of early rice crop seedlings is feverishly underway. Rice is China's principal grain crop and it is the early rice crop from which paddy rice yields per unit of area are fairly high and total output greatest. Consequently, a good job of early rice production holds major significance for assuring a bumper grain harvest for the year as a whole.

"When the seedlings are good, the rice will stand in the fields for half a year." Winning a bumper harvest from early rice this year requires, first of all the growing of sturdy seedlings. Long experience in production and the results of a large number of experiments attest that given the same conditions of growth and care, sturdy seedlings will produce yields of from several tens of jin to more than 100 jin per mu more than weak seedlings; ripening will take place from 3 to 5 days earlier; and savings in seeds and production costs can be effected. A rough calculation based on a low increase in yield shows that when seedlings are sturdy, increases in paddy yields for the year as a whole may amount to between 10 and 20 billion jin, and a saving of between 4 and 5 billion jin of seeds effected. A look at problems existing in seedling growing work right now shows that in this year's growing of sturdy seedlings, heavy emphasis should be placed on the following three things:

First close attention should be given to sparse sowing. This is fundamental in growing sturdy seedlings. Devoting too little land to seedling fields and sowing too many seeds on it remains a fairly common tendency. It is recommended that all jurisdictions vigorously promote Zhejiang Province's experiences with "one expansion and two decreases" (namely, expansion of the seedling field area, reduction of quantity of seeds sown in seedling fields, and reduction of quantity of seeds used in open fields in this year's propagation of rice seedlings, assuring that individual seedlings have an appropriate nutrient area, and that individual plants and plant colonies develop harmoniously.

Second, sowing should be done at the right time. This is a key measure in the prevention of seedling rot in the early rice crop. The main cause of early rice crop seedling rot is unwarranted stress on early sowing and early transplanting in a blind seeking after "earliness on top of earliness" with results that are just the opposite of expectations. How can one be sure of the right time for sowing? Many years experience everywhere suggests that once temperatures begin to rise in an area and stabilize at above 12°C, large scale sowing of early rice should be done. When heat insultation methods are used for the growing of seedlings, the sowing period may be advanced by about 10 days. In order to achieve sowing on time without seedling rot, communes and brigades in which economic conditions are fairly good should vigorously promote use of plastic mulch seedling propagation and some seedling propagation in hothouses.

Third is vigorous promotion of "many seedlings for a coherent whole." In a race against the season, in recent years many places have resorted primarily to a single planting of seedlings. New experience with a matching of "many seedlings for a coherent whole" with several plantings of seedlings permits the transplanting of young, tender, but sturdy seedlings in early crop fields, the transplanting of medium age seedlings in intermediate crop fields, and the transplanting of old, sturdy seedlings in late crop fields. This method permits making the most of advantages of various seedling propagation methods for the propagation of sturdy seedlings of proper age to meet crop rotation and variety requirements.

A good job of seedling growing requires establishment and perfection of a specialized seedling growing corps and designation of people responsible for care of seedling fields. Where conditions permit, seedling growing contract systems and seedling supply contract systems may be promoted. In the case of units practicing responsibility systems assigning responsibilities to households or teams, it is recommended that agricultural technique promotion units improve guidance given them on seedling growing techniques.

ACTIONS TAKEN TO BOOST HOG RAISING

Lanzhou GANSU RIBAO in Chinese 26 Mar 82 p 2

[Article by Gong Shifeng [7255 0013 6912] and Qiao Wangtang [0829 2489 1016]: "Reversal of Declining Trend in Live Hog Production. Qingyang Prefecture Takes Positive Action"]

[Text] The Qingyang Prefecture Commercial Bureau and Prefectural Food Company have taken possitive action to reverse the trend toward decline in live hog production throughout the prefecture.

As of the end of 1980, live hogs in inventory in Qingyang Prefecture numbered slightly more than 507,600, an all-time high. However, since the last half of 1981, a gradual decline has taken place in the number of live hogs in inventory in the prefecture. By the end of the year, the number had fallen to slightly more than 460,000 of which sows in inventory numbered only slightly more than 24,300, a number vastly lower than the sows in inventory at the end of 1980. The number of stud boars was also seriously inadequate. In order to reverse the trend toward decline of live hog in inventory, Qingyang Prefecture took the following several actions: First it devoted serious attention to an increase in the number of stud boars and sows to assure ample breeding stock. All commune members who raised boars and sows received a certain amount of fodder from the collective. Food units annually provided some cash subsidy for stud boars raised by commune members. Right now peasant households in communes and brigades in Heshui, Ning and Zhenyuan counties are in process of either actively buying or keeping stud boards and sows. Second, prefecture and county units concerned have done a good job of investigation, study, and forecasting work, promptly solving problems in live hog production, procurement, allocation, and transportation. During the busy season in live hog procurement, no depreciation of quality in order to drive down prices paid or covertly gyping the masses is permitted. Third was improvement of species and promotion of the breeding of fine breeds. Prefecture and county food companies worked hard in the operation of fine breed farms, gradually making fine breeds out of local sows and bringing in from elsewhere fine breeds of boars and hybridized meat hogs. Fourth was solution to the problem of coarse fodder processing for hogs raised by commune members. All the grinding equipment owned by food units were all turned to processing jobs for agriculture. Fifth, all county food procurement stations raised one to three stud boars to solve the commune members problems in breeding sows. Some procurement stations also raised sows, actively providing shoats to the masses. After these actions had been taken, the enthusiasm of the masses of commune members in the prefecture for hog raising rose once again.

PROVINCEWIDE SPRING AFFORESTATION CAMPAIGN REPORTED

Guangzhou NANFANG RIBAO in Chinese 3 Mar 82 p 1

[Article: "Surge of Afforestation in Cities and Countryside Throughout the Province. Seize Opportunity Provided by Spring Rains for the Greening of the Good Earth of Southern Guangdong"]

[Text] The cities and countryside in Guangdong Province have set off an upsurge in spring afforestation. As of mid-February, the province had raised more than 12,000 mu of saplings, a 43 percent increase over the same period in 1981. The area afforested amounted to more than 220,000 mu, a 67 percent increase over the same period in 1981. More than 3.7 million trees were also planted in the "four besides" [beside streams, roads, houses and villages], a tremendous increase over the same period last year.

Since last winter, accompanying gradual implementation of "three fixeds" in the province's forestry has been very high enthusiasm everywhere for afforestation. Many communes and brigades have devoted close attention to planning of forestlands, to preparing to plant seedlings, to making preparations for plowing and sowing and preparing the land for forestry, and going into the mountains to do afforestation following the lunar new year. The province's advanced unit in forestry, Jiaotan Production Brigade in Tangxi Commune, Fengshun County, has more than doubled its overfulfillment of afforestation plans for the entire year, each person planting an average of somewhat more than 120 trees. In Longchuan County, 90,000-odd commune member households planted 18,000 mu of trees on privately retained mountains.

Since the Provincial People's Government established the Greening Committee, 10 prefectures (or municipalities) and half the counties in the province have established greening committees. Statistics show that 370,000 people in the province are currently involved in a general obligatory tree planting campaign, and have planted more than 3 million trees in the afforestation of somewhat more than 1,500 mu. In Huiyang Prefecture, which acted most rapidly, more than 2.86 million obligatory trees have been planted, and the prefecture's Longshan County has already fulfilled its obligatory tree planting task. In Shaoguan Prefecture too, a total of more than 50,000 cadres in government organizations, staff and workers of plants and mines, and residents of streets have also gone out to plant more than 286,000 trees. Prefecture CCP Committee leaders led more than 1,000 government organization cadres, staff and workers, each one planting two or three trees.

Forestry units everywhere have actively helped communes, brigades and government units solve the problem of growing the saplings needed for afforestation, and they have buttressed technical leadership. All the communes and tree farms in Longmen County set up seedling nurseries to ready a sufficient number of saplings for spring afforestation. In addition to promptly supplying seedlings to each commune and brigade, forestry units in Yangshan and Shixing counties have organized forestry cadres and technicians to go to mountain region communes and brigades to help them do a good job of planning afforestation, to improve on-site technical guidance for afforestation, and to assure quality of afforestation.

TWO HYBRID RICE VARIETIES PROPOSED FOR CENTRAL, EASTERN GUANGDONG

Guangzhou NANFANG RIBAO in Chinese 25 Feb 82 p 2

[Article by Li Shanfa [2621 0810 4099], Provincial Department of Agriculture: "Prospects for Development of Hybrid Rice in Province's Central and Eastern Prefectures"]

[Text] Since the beginning of experimental planting of hybrid rice in Guangdong in 1975 until 1978, the growing of hybrid rice has spread over an area of 2,854,000 mu. In 1979, the area declined to slightly more than 1.8 million mu; in 1980 it again exceeded 2 million mu, and in 1981, it broke the 5 million mu mark. Despite last year's substantial development, growing was concentrated largely in Shaoguan and Zhanjiang prefectures, while very little was grown in the central and eastern prefectures. Can wide area growing of hybrid rice be promoted in these prefectures, particularly in the Pearl River Delta and on the Chaozhou-Shantou Plain? This is an important topic meriting study. It was for this purpose that I did some investigation and study combined with analysis of results of experiments during the past several years. I believe that all that is needed is selection for use of fine hybrid combinations plus the use of commensurate cultivation techniques and hybrid rice will spread fairly rapidly in the central and eastern prefectures.

The hybrid rice combinations selected for use in Guangdong Province between 1976 and 1978 were mostly "Nanyou" and "Aiyou." These combinations possess definite heteroses, but their resistance is low, and their yields are high but inconsistent. After summarizing the lessons of experience, the province virtually eliminated "Nanyou" and "Aiyou" beginning in 1979, switching to "Shanyou No 2," "Weiyou Nos 3 and 6" and Shanyou No 6." Year by year the growing area increased, and results in increased yields were outstanding. For example, at Lianshan Commune in Zhenghai County on the Chaozhou-Shantou Plain, where "Shanyou No 2" has been promoted ever since 1977, by 1981 its growing area had expanded from 1,300 mu to 7,100 mu, and yields rose from an average 866 jin per mu to 1,057 jin per mu, an increase of 86 to 190 jin per mu over conventional varieties. In 1980 and 1981, the early crop created high production records of 1,515.4 and 1,620.6 jin per mu respectively. Last year, Buxin Brigade, Huangjiang Commune, in Dongguan County planted 75 mu of "Shanyou No 6" as a late crop, harvesting yields averaging 859 jin per mu, a 302 jin per mu increase over yields from the local conventional sitting autumn variety, Guang'er 104.

For both "Shanyou No 2" and "Shanyou No 6," plant height ranges from 85 to 95 millimeters; tillering is moderate to strong, color is good during the late stage of ripening; branches are green and stems waxy; each panicle produces between 120 and 130 grains; and the fruiting rate is between 78 and 80 percent. Grown as an early crop, the total growing period for "Shanyou No 2" is about 135 days. Grown as a late crop, "Shanyou No 6" requires about 115 days. Their main characteristics are as follows: (1) Possessing fine bumper harvest properties; plants grow vigorously; tillering is early and rapid; and chlorophyll content of leaves is high. (2) Resistances are high, and disease and insect pest infestations are fairly light. "Shanyou No 2" is a combination with high resistance to rice blast and bacterial blight; it is also resistant to leafhoppers. In addition, it is rather strongly adaptable to temperature and light. For "Shanyou No 6," when weather is overcast and chilly, not favoring flowering, spikelets delay flowering, their restraint lasting 1 or 2 days. (3) Adaptability is broad. They may be grown as both early and late crops on coastal plains, in hills and in mountain areas, or in sandy, clayey or black muddy soils, and they have fairly high potential. (4) They help in the accentuation of strengths and the playing down of weaknesses to make the most of advantages. According to briefings, after the "Shanyous" have been transplanted, tillering occurs between 22° and 29°C (centigrade used throughout), a direct proportional relationship existing between speed of tillering and temperatures. For the early crop, temperatures in central and eastern prefectures between Qingming [around 5 April] and the Grain Rains [around 20 April] are between 21.7 and 25.5°. For the late crop, around the time of Autumn Begins [around 7 August], temperatures are between 27.8 and 28.4°. Therefore, either as an early or a late crop, most places have suitable temperature conditions for tillering.

The "cold dew wind" is the most damaging kind of weather for the late crop, and it poses a great threat to late crop output. According to meteorological data for the central and eastern prefectures, for an 80 percent rate of assurance the period of full heading should come before 5 October. So long as we arrange for the full heading period to be before 30 September, consistently high yields can be harvested a substantial amount of the time. Additionally, during the late stages of the late crop, night and day temperature variations are great, which is very beneficial for coming into milk, for fruiting and for increasing rice grain weight. Therefore, so long as the central and eastern areas properly arrange the combinations, using "Shanyou No 2" for the early crop, planting it in late February for heading and flowering in mid-June, full use can be made of light and temperature conditions at the time to avoid the cloudy and overcast days of the "dragon boat rains" [of June]. For the late crop, "Shanyou No 6" should be used, sowing done during the first 10 days of July for transplanting at the end of July or early August, and full heading taking place in mid-September to completely avoid the "cold dew winds." This will play a very great role in changing the situation of low and inconsistent yields from the late crop.

MAJOR IMPROVEMENTS IN FARMLANDS REPORTEDLY UNDERWAY

Guangzhou NANFANG RIBAO in Chinese 25 Feb 82 p 1

[Article: "Guangdong Province's Mountain Region Communes Start an Upsurge in Restructuring of Low Yield Fields. Increase Grain Yields Per Unit of Area and Develop Mountain Region Economy"]

[Text] Last winter and this spring, more than 450 communes in Guangdong Province have set off an upsurge in agricultural capital construction centering around the restructuring of low yield fields. According to most recent statistics, 570,000 mu of low yield fields have already been restructured, with the movement of 8.33 million cubic meters of earth and stone.

Since 1979, rural villages everywhere in the province have comprehensively tackled water, soil and fertility in the restructuring of more than 2.8 million mu of low yield fields. This plus other scientific farming measures has brought about tremendous increases in grain production from these fields. Yields per mu per year have thereby increases almost 100 jin at the minimum and between 200 and 300 jin at the maximum. Now the focus of restructuring of low yield fields has shifted away from the plains and hilly areas to mountain regions where it is being carried out on the basis of universal practice of responsibility systems whereby responsibilities are assigned on a large scale. Consequently all levels of party CCP committees have strengthened leadership for this work, and have concentrated financial and material resources on the restructuring of low yield fields in key communes and brigades. They have also sent large groups of cadres to help out in the countryside, thereby turning the restructuring of low yield fields into a conscious mass movement. In Meixian Prefecture, key communes for the restructuring of low yield fields generally have from five to seven cadres specially in charge of this work. Zhaoqing Prefecture sent more than 600 commune cadres and more than 400 agricultural science personnel to give on-the-ground technical guidance.

While restructuring low yield fields, all jurisdictions devoted attention to the adaptation of general methods to local situations, to comprehensively tackling problems, to doing tailored restructuring, both paying attention to changes in low yield field production conditions and paying attention to a combination of harnessing mountains and slopes to improve the ecological environment, assuring project quality, and improving economic benefits. At the same time all jurisdictions were sure to follow the principle of acting in accordance with capabilities, doing everything within their power, "the people acting with public support" and following a policy of voluntary participation and mutual benefit to arouse mass enthusiasm for restructuring of low yield fields. Since last winter, funds provided by communes and brigades throughout the province have totaled more than 12.6 million yuan, or 53 percent of project expenses. Foshan Prefecture allocated 3.45 million yuan of local public funds to support peasant restructuring of low yield fields. Subsequently, each county in the prefecture disbursed 1.08 million yuan of local public funds for restructuring of low yield fields. These allocations, plus 3.87 million provided by communes and brigades themselves, have meant fairly good solution of need for funds to restructure low yield fields.

FOSHAN PREFECTURE EMPLOYS ADMINISTRATIVE, TECHNICAL MEANS TO INCREASE OUTPUT

Guangzhou NANFANG RIBAO in Chinese 18 Feb 82 p 1

[Article by Reporter Tao Guangyuan [7118 0342 0337] and Correspondent Mian Hao [0517 3185]: "Foshan Prefecture CCP Committee Adopts Five Measures to Do a Good Job of Grain Production. Stabilizes Existing Grain Area and Actively Develops Economic Diversification"]

[Text] At a recently convened meeting of county and municipal CCP committee secretaries, comrades in charge of the Foshan Prefecture CCP Committee noted that, "It is currently necessary to strengthen national concepts, overall situation concepts and planning concepts, carry out an all-around production program of 'positively no slackening of grain production while actively launching economic diversification,' and adopting energetic measures to do a good job of spring farming and production."

Since the 3rd Plenary Session [of the 11th Party Central Committee], uncer the guidance of the state plan, Foshan Prefecture has adapted general methods to local situations in the readjustment of its agricultural production patterns, and has changed the former rather unitary economic structure for substantial development of economic diversification and of commune and brigade industrial sideline occupations. The Prefecture CCP Committee believes that the past several years' readjustment of the prefecture's agricultural production patterns has been very necessary, that steps have been measured and results outstanding. A look at the present situation shows the broad masses giving extraordinary attention to development of the livestock industry, the fishing industry, to cane sugar, oil-bearing crops, fruit production, commune and brigade enterprises, and household sideline occupations. Such enthusiasm is very precious and should be given support and protection as well as practical guidance and help. However, among some cadres and the masses an actual tendency to ignore grain production exists. Zeal for development of economic crops and engaging in industrial sideline occupations is great, while zeal for grain production is not as great. Some even care nothing for state plans, taking it upon themselves to make major reductions in the grain growing area in a change to the growing of other crops. In order to assure fulfillment of grain and other production tasks handed down by the state this year, timely ideological education of the broad masses of cadres and people must be carried out to help them firmly establish a national concept, an overall situation concept, and a plan concept and to consciously take grain production firmly in hand. For this purpose, the Prefecture CCP Committee proposed attention to the following several measures:

1. Wide publicity to the carrying out of ideological arousal, with much playing up of the importance of grain production. Everyone should come to understand that Foshan Prefecture is a major commodity grain base in the province, and that providing the state with sufficient commodity grain is a duty to which we should bend every effort, and that this is also necessary for stabilization of the overall situation. We should not only calculate that the price paid for growing grain is not as high as for other crops, or that income from the investment of labor in grain production is not as great as from doing industrial sideline work; rather we should conscientiously calculate that only by doing a good job of grain production is it possible to develop industrial sideline occupations without nagging worries about food, and only then is it possible to have larger amounts of livestock feed for development of a collective and household livestock raising industry, and a breeding industry, and only then can the already readjusted agricultural production pattern be placed in an invincible position. Additionally, cadres and the masses should be made to understand that China today is still not prepared entirely to use prices to regulate production conditions. Producers in our socialist country cannot rely solely on laws of value to engage in production. Were each trade and industry to function according to amount paid, the state plan would be thrown into turmoil to the serious impairment of our production and our lives. Therefore, all places that lend themselves to the growing of grain must take cognizance of the overall situation, care about the general interest, and grow grain crops in accordance with state plans.

2. Strengthening of plan guidance and stabilization of existing grain growing area. There is need for active promotion of economic contracts and the use of economic contracts and such methods to dovetail state plans with collective and individual commune member production activities, so that state plans will be implemented in every production unit. The paddy rice growing area throughout the prefecture must be stabilized at between 4.4 million and 4.5 million mu so that a fairly reliable foundation will exist for increase in the prefecture's total grain output.

3. Use of various kinds of economic methods to arouse peasant enthusiasm for grain production. Preparations for farming and spring farming must both be combined with further advances and improvements in various forms of production responsibility systems, the peasants thereby deriving material benefits from the contracting of grain production. There must be further promotion everywhere of the use of the methods of using industrial sideline occupation profits to subsidize agriculture, and use of economic crops profits to subsidize grain production to stimulate grain production.

4. Widespread promotion of hybrid rice, use of mixed nitrogenous, phosphate and potash fertilizers and such advanced agricultural techniques in an effort to increase yields per unit of area. Energetic advocacy of the agricultural science

and technology contracts system promoted in Guizhou Commune, Shunde County, and the popularization of agricultural science and technology so that agricultural research results will be rapidly transformed into productivity. Advocacy that all levels of leadership go down into the grassroots to launch scientific experiments and to arouse youths, militia and women to large-scale cultivation of experimental fields and high yield fields.

5. Mobilization of all trades and industries to assist agriculture and support grain production.

RUBBER DEVELOPMENT, OUTPUT REVIEWED

Guangzhou NANFANG RIBAO in Chinese 17 Feb 82 p 1

[Article: "Substantial Development of Commune and Brigade Rubber in the Province. Last Year's Output of 8,000 Tons of Dry Rubber, Plus State Farm Output Brought Province's Total Output to More than 100,000 Tons"]

[Text] Substantial development has taken place in the growing of rubber by the province's communes and brigades. The province's commune and brigade rubber growing area now stands at 1 million mu, with slashing being done on 270,000 mu. In 1981, dry rubber output was 8,000 tons, more than doubling the 1976 output. This plus state farm output meant that the province's total output of dry rubber broke the 100,000 ton mark in a year that saw unprecedented development of rubber.

In some communes and brigades along the seacoast of continental Guangdong and on Hainan Island, the climate is mild and rains copious, suiting them to the development of rubber production. As a result of the former influence of "leftist" ideology, production teams were permitted to grow grain only, and were not allowed to develop rubber. As of 1976, the province's commune and brigade rubber output was still less than 4,000 tons. Following the 3rd Plenary Session of the 11th Party Central Committee, while doing a good job of grain production, numerous communes and brigades allocated workforces and put out the funds for development of rubber production. On Hainan Island, most communes in every county grow rubber. Along the continental seacoast, some communes and brigades have also cultivated new rubber varieties that stand up to the wind, tolerate coldness and are suitable for growing locally, and have started up rubber plantations. Today communes and brigades in 38 counties grow rubber.

Everywhere state farms have actively assisted communes and brigades in the development of rubber production. This has both solved commune and brigade difficulties with insufficient funds, and has solved a conflict in production between the state farms and communes, both state farm and commune and brigade rubber production achieving common development thereby. As a result of the development of rubber production and of other economic diversification endeavors, many rural communes and brigades have changed their unitary economic structure, have strengthened the collective economy, and commune member distributions have become increasingly high.

Shiwu Production Brigade on Hainan Island grows somewhat more than 5,680 mu of rubber, producing more than 200 tons of dry rubber annually for earnings of more than 1.1 million yuan. Its earnings from rubber account for 72 percent of the brigade's gross income. During the past several years they have produced 1,900 tons of dry rubber for the country, paying 240,000 yuan in rubber revenues. In addition, the brigade has accumulated more than 5 million yuan of public accumulation funds and public welfare funds.

GUANGDONG

BRIEFS

RURAL SAVINGS UP--Rural savings deposits in Guangdong Province this year continued to demonstrate a tendency toward tremendous increases. As of the end of January, rural savings deposits in the province totaled more than 2.76 billion yuan, which averages out to savings deposits of 57.40 yuan per capita of the agricultural population. In January of this year alone, savings deposits increased at an average 5.20 yuan per capita. This shows that the province's rural economy is booming, and that the living standards of the broad masses of peasants are steadily rising. DEVELOPMENT OF FORESTRY SAID STRATEGIC STEP TO BUILD UP FLATLAND

Shijiazhuang HEBEI RIBAO in Chinese 5 Feb 82 p 2

[Article by Zheng Zhaoxiang [6774 0340 4381], Jiao Zhigeng [3542 1807 5087], and Cao Peng [2580 7720]: "Developing Forestry Is a Strategic Measure To Build Up the Flatland"]

[Text] Readjusting the policy of economic buildup must be based on the period required to realize economic gain so that visible economic results can be achieved within a relatively short period. At the same time, we must start out from long-range ecological effects in our efforts to restore the natural ecological environment which has been destroyed and we must put efforts to further cultivate and protect resources in first place. Therefore, planting trees and forestation in a big way and developing forestry production are strategic measures to build up the flatlands.

Zhangbei County in the flatlands had little forest land at the beginning of the founding of the nation, but vegetation of the meadows was good. In 1949, 2.87 million mu of grassland were recorded and permanent vegetation constituted 57 percent. The coverage of vegetation was good and the ecological environment was stable. After the arrival of the 1960's, massive reclamation and planting destroyed the vegetation and caused environmental factors to change. One was the frequent damage by wind and sand. Comparison of the 1950's and the 1970's shows that the annual average wind speed increased 0.8 meter/second. The average number of days of strong wind increased 36.8 days. The number of days of sandstorms increased by 3.4 days. The area of wind erosion throughout the county covered about 610,000 mu. From April to May of 1972, strong winds about 7 on the scale blew for 27 days. Farm crops of more than 500,000 mu throughout the county were damaged and 150,000 mu of land were forced into destruction. The second was the worsening of drought. During the 25 years from 1956 to 1980, drought occurred in 21 years and major drought occurred in 2 years, indeed 9 years of drought out of every 10. The third was soil erosion. Because the slopes were overly reclaimed, the area of soil erosion throughout the county has already reached more than 2.2 million mu. Each year, more than 960,000 mu of soil are eroded. Especially in recent years, floods due to a rush of mountain water have gradually increased. In 1979, 119,000 mu of farmland of 94 brigades belonging to 10 communes in the mountain areas were covered by sand washed away by water. Detrimental changes due to ecological imbalance cannot be remedied by man. Facts show that adjusting the internal structure of agriculture must start from restoring and retaining the ecological balance and from planting trees and forestation in a big way.

Forestry production is an important component of the natural economy of the flatland. Since founding of the nation, the area preserved by artificial forestation in Zhangbei County has reached 615,900 mu. Even though the present level of forestation is relatively low, the total reserve of forests has reached 183,000 cubic meters. Each person has half a cubic meter of forest wood throughout the county. Analytic calculations of tree trunks show that each year, the growth rate of the reserves of forest wood is over 20,000 cubic meters and the value of natural growth is about 4 million yuan.

In addition, there is an extreme shortage of energy for living in the farm villages on the flatland, and firewood is still a difficult and lingering problem. For example, many farm families in the farm villages of Zhangbei County basically rely on stalks of crops and manure of cattle and horses. At present, this county has forested more than 60,000 mu. According to plans, by 1985, each family will have an average of 3 mu of firewood forest land and the problem of firewood for farmers will be basically solved.

To quickly restore the ecological balance in the flatlands, forestry production must be rationally distributed. The foremost purpose of foresting the flatland should be the protection of gain, and the pursuance of economic gain should be second. Accordingly, in the distribution of forestry production, the retention of soil should be the main effort in the mountain regions and breaking the wind should be the main effort in the plan. In the plains, forestation of the river systems should be developed in a big way. Land of the "four sides" should be planted well. The gaps should be filled so that a whole system of effective protection that is connected by expanses, networks and strips can be formed within a short period. In the mountain regions and hilly regions, forests that retain water and soil should be greatly developed. The area of coverage should be actively increased. Damage to mountain areas and after-effects detrimental to the plains should be overcome.

STABILIZATION OF GRAINFIELD AREAS SOUGHT

Shijiazhuang HEBEI RIBAO in Chinese 6 Apr 82 p 1

[Article: "Take Action to Stabilize Grainfield Area to Assure Increased Grain Output. Provincial Government Approves and Sends to Provincial Bureau of Agriculture 'Report on Stabilization of Grainfield Areas to Assure Increased Grain Output,' Requiring all Prefectures, Municipalities, and Counties to Take Each of the Actions Contained in the Report"]

[Text] Recently the Provincial People's Government approved and passed on to the Provincial Bureau of Agriculture the "Report on Stabilization of Grainfield Areas to Assure Increased Grain Output," which requires all prefectures, municipalities, and counties, on the basis of local situations, to diligently study and conscientiously carry out the various actions contained in the report for assuring this year's grainfield area and increases in grain production.

A provincial government memorandum requires each jurisdiction to diligently put into effect a program of "positively no relaxation of grain production while actively launching economic diversification," and "taking the planned economy as primary and regulation by market mechanism as secondary" in all-around fulfillment of this year's planting plans for grain, cotton, oil-bearing crops, and other economic crops. The growing area for grain grows is to be stabilized and main attacks directed against yields per unit of area to assure fulfillment of plans for a grain output totaling 33 billion jin. Right now it is necessary to give attention to "one resistance and double guarantees," first of all winning a fine summer harvest while at the same time doing a good job of spring sowing to win another all-time high in autumn grain output.

The Provincial Bureau of Agriculture report said that since the Third Plenary Session [of the 11th Party Central Committee], all of the province's jurisdictions have diligently carried out a program of "positively no relaxation in grain production while actively launching economic diversification." They have gradually readjusted agricultural crop patterns and have continued to reap rather good harvests despite the unfavorable conditions of 3 consecutive years of drought. A comparison of 1981 with 1978 shows a downward readjustment of the grain growing area from 76.6 million mu to 73.5 million mu, a decrease of somewhat more than 3 million mu. However, total output has continued at 31.5 billion jin. The year 1981 was the third all-time high year, only the great bumper harvest years of 1978 and 1979 being better. From a cottonfield area of 8 million mu, output totaled 450 million jin, a 92 percent increase. Ginned cotton yields averaged 56 jin per mu, making 1981 the fourth highest year for production. The oil-bearing crop area was increased to 7.42 million mu, an expansion of 2.9 million mu. Output totaled 928 million jin, an 89 percent increase for an all-time high. Other economic crops and economic diversification showed varying degrees of increase. This year, in accordance with the principle of "adaptation of general methods to local situation to make the most of advantages," plans call for expansion of the province's cottonfields to 11 million mu, a 3 million mu increase over last year. Smaller increases are also planned for other economic crops. Calculations on the basis of the agricultural production plan handed down by the province show an additional somewhat more than 70 million mu as the province's grainfield area. This plan is a suitable one and is to be guaranteed fulfillment.

The notice pointed out that a problem currently deserving of attention is that in some places a tendency toward paying no attention to state plans, blindingly expanding the growing of economic crops, and reducing the grainfield area has appeared. This year all jurisdictions have reported assignment to production teams of an area of 11.23 million mu for the growing of cotton in the province. Jurisdictions have reported the growing of 7.62 million mu of oil-bearing crops when plans call for the growing of 7.45 million mu. The actual acreages are even larger. In some counties, communes, and brigades, the area planted to economic crops such as cotton and oil-bearing crops exceeds by 20 to 30 percent plans handed down by the state. As a result of their growing of diverse economic crops, some places want to rely on the state to bring in grain from elsewhere, and some plan on increasing their earnings through development of economic crops and buy grain in markets. Such thinking is wrong and dangerous; it can cause hardships for the country and the people. Ours is a large province with a population of more than 50 million, which has to be self-sufficient in grain. The province's circumstances require that in order to assure consistent increases in total grain output, it is necessary both to increase yields per unit of area and to maintain a certain grainfield acreage. This year's plan calls for a grainfield area for the province that is 6 million-odd mu less than in 1979. If the economic crop growing area is blindly expanded further, the province's 70 million mu of grainfields cannot be guaranteed. All levels of leadership should arouse a high degree of serious attention to this problem and stabilize the grainfield area above 70 million mu to assure increases in grain output.

In order to realize a planned total output of 33 billion jin of grain for the province this year, the report requires that all jurisdictions should proceed from a foundation of perfecting production systems of responsibility and arousal of mass enthusiasm to give diligent attention to the following points:

1. Diligent implementation of a program of "positively no slackening of grain production while launching economic diversification," and "taking the planned economy as primary and regulation by market mechanism as secondary" to intensify planting in accordance with state plan, arranging at the same time for grain crops and economic crops. This year the grainfield area for the province as a whole cannot be less than 70 million mu. The cottonfield area is to be 11 million mu, and the oil-bearing crop area is to be 7.45 million mu, and planting

should be done according to plan in sufficient quantity and quality. Every effort should be made to use idle land for the growing of some non-staple economic crops. All jurisdictions are to centrally program the area to be sown to grain, cotton, oil-bearing crops, and other economic crops in accordance with state plans that have been handed down. The broad masses of cadres and people are to be indoctrinated in establishment of plan concepts and concepts of the situation as a whole, taking into consideration the welfare of the country, the collective, and individuals. Guided by the state plan, there should be an equitable distribution of grain crops and economic crops, one advancing the other in coordinated development to gain better economic benefits.

2. Diligent implementation of the assignment of sole responsibility for state grain tasks, the signing of economic contracts being taken firmly in hand. Beginning this year, Hebei Province will use the method of assumption of sole responsibility for grain requisition procurement, sales, allocation and transportation, so all jurisdictions are to use the signing of economic agreements as a means of implementing level by level the assumption of sole responsibility for grain quotas. So long as fulfillment of sole responsibility grain quotas can be assured, equitable provisions for this year's planting plans can be made that both guarantee fulfillment of state plans, respect production team self-determination, and bring more into play the enthusiasm for production of the broad masses of commune members.

3. Simultaneous with the stabilization of growing areas, efforts are to be made to increase yields per unit of area. It is necessary, first of all, to win a good summer harvest. All jurisdictions are to strengthen leadership and launch a principal attack on yields per unit of area in an effort to achieve a summer grain output that matches or exceeds last year's. In addition, attention is to be directed to combat drought to do spring planting to assure autumn grain production. Arrangements for autumn grain crops should help increase yields per unit of area and increase total output. Hill drylands should grow more millet and sweet potatoes, and low-lying areas should grow more gaoliang. Corn output accounts for half the fall grain. Except for places not suitable for the growing of corn, there should be no excessive reduction in corn acreage. Every effort should be made to encourage the intercropping of pulses with corn and gaoliang. Ability to stand up against disasters and assure outputs can be increased through equitable crop patterns. The masses should be stirred to make full use of idle land to try to grow more grain. All jurisdictions should focus on "one resistance and double assurances" to do a good job of technical promotion work. They should organize large groups of technical personnel to go down to the grassroots to help improve work and gain firsthand experience, actively sign technical promotion contracts linked to output, and begin technical teaching in order to raise the scientific farming levels of the broad masses and promote increased output of grain this year.

NEED TO GUARD GRAINFIELDS FROM FURTHER ACREAGE REDUCTIONS STRESSED

Shijiazhuang HEBEI RIBAO in Chinese 2 Apr 82 p 2

[Article by Lu Shuangcai [6424 7175 2008] and Yang Zingfa [2799 5281 4009]: "Hebei Province's Grain Acreage Should Be Stabilized"]

[Text] In the process of readjusting agricultural crop patterns since the Third Plenary Session [of the 11th Party Central Committee], Hebei Province has corrected the mistaken past method of "taking grain as the key link and cutting everything bare," crop patterns for grain cotton, edible-oil and other economic crops tending toward equitability. A problem that merits attention now is the tendency toward great decline in the grainfield area. This problem must arouse a high degree of serious attention on the part of leaders at all levels to take effective action to stabilize the grainfield area in Hebei Province.

As a result of the institution of various forms of production responsibility systems during the past 2 years, the enthusiasm for production of commune members has been aroused, and the grain situation in Hebei Province has taken a turn for the better. But life is still hard. The province has a population of more than 50 million, so getting enough to eat is a matter of primary importance. Since the founding of the People's Republic, grain production has seen fairly great development; however, it is still far from ample. During the 29-year period between 1953 and 1981, only 4 years produced a grain surplus; in the other 25 years there was shortage during which more than 27.6 billion jin of state-transported grain was consumed. Looked at in terms of average amount per capita, in 1979 each person had 619 jin of grain, an all-time high; yet this was lower by 69 jin than the national average. During the last 2 years, average per capita grain consumption has not increased. In 1980, it was slightly more than 500 jin; in 1981, it was 605 jin. At the same time, the province's production has not been consistent. In bumper years, the situation is a little better, but a lean year means reduced grain output, and use of grain by everyone becomes a little tighter. Consequently, it is absolutely impossible to relax grain production.

Quite a few comrades suppose that once the grain field acreage has been reduced, total output can be assured by increasing yields per unit of area. We acknowledge that this method can solve some problems and that the future orientation has to be a concerted attack on per unit yields. However, under present conditions, a sudden very great increase in yields per unit of area is also not realistic. During the past several years, grain yields in Hebei Province have been in general somewhat more than 400 jin per mu. In 1978 and 1979 when yields per mu were highest, they were 440 jin and 474 jin respectively. This year's planned total grain output is 33 billion jin. Figuring a grainfield area of 70 million mu, that means yields per mu will have to reach somewhat more than 470 jin if the plan is to be realized. If the acreage is less than 70 million mu, then the yields per mu will have to be somewhat higher. In 1979 both the summer and the autumn harvest were bumper ones with high average yields per mu. This year's task of getting somewhat more than 470 jin per mu yields of grain will be an arduous one. That is because this year's wheat acreage is 4.6 million mu less than the previous one, and again there is protracted drought with no rain. Beginning this year, the Central Committee has instituted the assumption of sole responsibility by Hebei Province for grain allocations, guaranteed to remain unchanged for a 3-year period. Therefore, we must stabilize the grain acreage and use every available means to make a main attack on yields per unit of area in an effort to fulfill this year's increased grain production plan.

Readjustment of agricultural crop patterns will be limited by grain. Formerly the province onesidedly stressed taking grain as the key link to the detriment of economic crops. High yield poor brigades came into being, and in some places not only were grain crops elbowed aside, but no increase in grain output occurred either. In recent years, as a result of readjustment of agricultural crop patterns, the cotton acreage has increased from 1978's 8 million mu to this year's planned 11 million mu. The edible-oil growing area has increased from 4.5 million mu to 7 million mu, and the acreage for other economic crops has also increased. If the grainfield development of economic diversification occurs to the detriment of grain, and this will also create an imbalance in agricultural crop patterns. If total grain output declines, economic crops will not be able to go up either. Therefore, in readjusting agricultural crop patterns, it is certainly necessary to consider this premise, and it is necessary to be restricted by grain.

Ours is a socialist country in which the entire national economy is predominantly a planned economy, regulation by market mechanism being secondary. Agricultural production is no exception. Following the institution of various forms of production responsibility systems in agriculture, it continues to be a collective economy founded on the public ownership of the basic means of production such as land. In drawing up production plans, the guidance and restraints of state plans must be accepted. Therefore, when formulating planting plans implementation of state grain production plans must be assured as must the fulfillment of tasks in assumption of sole responsibility for requisition grain procurement. There can be no planting as one pleases. Only by assuring a certain grainfield acreage will it be possible to assure steady increase in total grain output, the entire national economy thereby having planned, proportional, and coordinated development.

PIG RAISING ON RISE IN SOME COUNTIES

Shen County

Shijiazhuang HEBEI RIBAO in Chinese 29 Jan 82 p 1

[Article by Duan Zhencang [3009 2182 5547], Kang Bingqiang [1660 3521 1730], Pang Fusen [1690 4395 2773]: "Grasping Well the Demonstration Families Led Thousand Families and Ten Thousand Families, the Number of Hogs Raised in Shen County Rose Month By Month"]

[Text] Shen County started out from the new situation after popular implementation of the production responsibility system in farm villages, carried out the method of grasping well the "demonstration families" to lead the broad masses and encouraged commune members to raise hogs.

After the broad number of farm villages in Shen County popularly implemented the various forms of the production responsibility system, and under the effect of past years when submitting hogs was difficult, the number of hogs raised by the collective production teams decline. Some commune member families paid more attention to family planting under the prerequisite of planting the fields they were responsible for well, and raising hogs by the families suffered to a definite degree. To solve these problems, the county committee, the county people's government and the livestock production department established "demonstration families" and assigned them to cadres according to districts. And beginning from last year, cadres were assigned the responsibility of overseeing such families to develop hog raising and to promote hog raising by the many families in the country. Hog raising by commune members thus developed again. The actual method was first to establish the 86 commune member families who raised and submitted more than 5 fattened hogs a year or who raised more than two head of sows a year as hog raising demonstration families. Over 40 technical cadres of the county livestock bureau and 35 commune veterinary stations took charge of these demonstration families separately and actively popularized scientific formulas for feed, prevented and controlled diseases in time, and truly guaranteed healthy growth of the hogs. This enabled the hog raising demonstration families of the whole county to exert a profound influence upon the masses and more than 10,000 commune member families began actively raising hogs again. The number of hogs in the whole county thus increased month after month. Statistics up to the end of last year showed that during the whole year, the number of hogs raised reached over 199,700 head, an average of 1.8 head per family and approaching the highest level in the past. More than 93,000 hogs were released from the pens, an increase of 2,024 head over the previous year. Up to the present, the whole county has more than 100,000 head of hogs in pens.

Zunhua County

Shijiazhuang HEBEI RIBAO in Chinese 4 Feb 82 p 1

[Article by Xu Fengci [1776 7685 3069], Ren Youdou [0117 2589 2435], Cui Haifang [1508 3189 2387], and Wang Shouben [3769 1343 2609]: "Adapting to the New Situation Created by the Production Responsibility System, Adjusting the Method of Reward for Raising Hogs, the Number of Hogs in Zunhua County Continues To Increase"]

[Text] The Zunhua County Committee conscientiously analyzed the reasons for the drop in the number of domesticated hogs and actively adjusted the method of rewards for raising hogs. These efforts have rapidly changed the decline in the number of hogs raised and have increased the number. At the end of last year, there were 280,000 hogs in pens throughout the county, and increase of 20,000 over the number at the end of 1980. Each family raised an average of 2.3 pigs.

At the beginning of last year, the county committee discovered that the number of hogs raised throughout the county dropped. The number of fattened hogs shipped out from the whole county dropped by 9 percent from the same period the year before last. Some localities suffered a drain of their breed hogs. The number of sows also declined by more than 500 from the middle of the previous year. They analyzed the causes of the decline in the number of hogs raised. One reason was the decline in the amount of feed rewarded to hog raising. In the past, for each hog raised by commune members, the state and the collective generally rewarded over 400 jin of feed. Now, some commune brigades only receive about 300 jin. This raised the cost of raising one hog by 3 to 5 yuan. The second reason was that the number of work points rewarded by the collective for hog raising and the number of work points rewarded for manure fertilizer declines. In the past, for each hog raised by commune members, they received about 1,000 work points a year. If we calculate on the basis of 5 jiao per work point, cancelling the work points would reduce the income per hog by about 50 yuan. According to surveys, after implementing the production responsibility system, 554 production teams of the more than 3,400 throughout the country received less work points for raising hogs and for providing manure fertilizer, and rewards of food grains for raising hogs were cancelled for 958 production teams. In this way, the cost of hog raising increased, income dropped and commune members could not benefit. The enthusiasm for hog raising suffered a serious setback. Aimed at this situation, the county committee conducted a special study of the problem of raising hogs, and issued the following rules concerning hog raising policies according to the different forms of the production responsibility system:

1. Production teams that implement unified management, distribution and contract work and production to teams or to individuals should generally award work points to hog raising families and work points to commune members

providing manure. Hogs weighing less than 40 jin should be awarded half a work point each. Hogs weighing more than 40 jin should be awarded one work point each. Each sow should be awarded three work points. For each hog that has been raised from the young to the time it is removed from the pen and the time when its manure accumulates to 7 to 8 cubic meters, about 70 work points should be awarded per cubic meter of manure. In awarding food grains for hog raising, 1 jin of food grains should be awarded for every 10 work points accumulated by a commune member raising hogs.

2. Production teams implrmenting the system of responsibility for food grain fields and economic crops should award one work point a day to any commune member who raises one hog weighing more than 20 jin and the manure submitted to the collective should be paid for according to quality. Feed grains for hog raising follows the general rule of "1 jin of feed per jin of weight per hog." The amount of feed grains which should be received for raising and fattening hogs determines the size of the plot of land for planting feed grains, and this plot is to be managed individually by the commune member.

3. Production teams that implement the system of contracting production to the families and contracting work to the families will not procure manure from hogs raised by commune members anymore. The commune members are only given feed grains for hog raising. There are two says: One is that the production team uniformly distributes food grains as subsidy according to the number of jin gained by the hogs raised by a family. The second is to determine the amount of feed grains according to the number of jin gained by the hogs, then, a plot of land whose size is appropriate for producing the amount of feed grains thus determined is assigned to the commune member. Generally, a feed plot of 1 fen 5 li is assigned for every head of hog raised from young to the time it is fattened. Two fen of feed plot are assigned for every sow. The plots are managed and used by the commune members themselves.

After establishing these rules, the amount of feed grains received by commune members for raising one hog in the county equals the amount received prior to implementation of the production responsibility system. The income of the hog raising family from the collective has not reduced. Commune members said: "This time, the hog raising policy is implemented anew, and there are more real benefits from raising hogs, so why should we not raise more hogs?" The enthusiasm of the broad number of commune members and masses in raising hogs has been mobilized, and the hog raising industry through the county has rapidly shown new development.

HANDAN PREFECTURE PROMOTES SCIENCE, TECHNOLOGY IN AGRICULTURE

Shijiazhuang HEIBEI RIBAO in Chinese 3 Feb 82 p 1

[Article by Yang Zhijun [2799 1807 6511] and Li Rishan [2621 2480 1472]: "Popularize Science, Satisfy Farmers' Needs, Handan Prefecture Strengthens the Agency To Popularize Agricultural Techniques"]

[Text] After the Handan Prefecture implemented the agricultural production responsibility system in the farm villages, a new situation of learning science, loving science and using science emerged. The broad masses of farmers urgently want to learn scientific techniques and utilize scientific techniques to guide production, seize bumper harvests and become rich. The committee of the Handan Prefecture and the administrative office have decided to restore and make sound the science and technology agency in face of this new situation. Each city and county established a science committee and a science association and many special societies, and the agricultural and forestry departments of the prefecture, cities and counties established technical stations, plant protection stations, soil fertility stations, veterinary stations, seed companies and superior seed farms. Some counties also established county agricultural science institutes and science and technology centers. Throughout the prefecture, 391 communes established superior seed farms, and 1,341 brigades established small farms. The agricultural science and technology department at each level cooperated together and propagandized and popularized agricultural science and technology in broadcasts and lectures, by posting bulletins in farm villages, and at night schools for farmers. The technical cadres of many county communes signed joint technical contracts with production brigades, production teams and responsible families and work teams. At the same time, the whole prefecture also popularized demonstration farms for scientific planting and scientific raising of animals, and it popularized the experience of demonstration families. Visible results were realized. In 1980, the whole prefecture planted 590,000 mu of lumian No 1 cotton. In 1981, this expanded to 1.2 million mu. Hanza No 1 corn increased from 23,000 mu to 246,000 mu. Pingsanjiu wheat increased from 220,000 mu to over 600,000 mu. The technical and management level in the cultivation of major farm crops, in the prevention and control of cotton diseases and insect pests, in forestry, in livestock production, in aquatic production and in family sidelines all improved greatly.

POLYESTER COTTON CLOTH PRODUCTION CUT BACK

Shijiazhuang HEBEI RIBAO in Chinese 24 Mar 82 p 1

[Article by Qian Yongsheng [6929 3057 3932]: "Provincial Textile Bureau Scales Down Polyester Cotton Production Plans While Increasing Pure Cotton Cloth and Low Proportion Chemical Fiber Products"]

[Text] In order to meet developing needs of the people's livelihood and strive to increase economic benefits, recently the Provincial Textile Industry Bureau readjusted product structure, scaling down polyester-cotton cloth production plans for this year while increasing output of pure cotton cloth that is currently in short supply in the market and which sells at the right price, and of cloth that is a blend of cotton and a low proportion of chemical fibers that enjoys sales in rural villages.

The downscaling of polyester-cotton cloth production plans was done on the common basis of last year's production of polyester-cotton cloth by textile industries throughout the country and market sales. The province's output of polyester-cotton cloth has been cut by 43 million meters from original plans, and corresponding reductions have been made in miscellaneous polyester-cotton cloth. Following the downscaling of polyester and cotton cloth production plans, production is to be strictly controlled according to plan. Superficially it appears that gross output value of the province's textile industry will be somewhat impaired; however, this measure should get rid of some fat so that the speed of development will be more solid. Furthermore, depending on market requirements, production of pure cotton products and products with a low proportion of chemical fibers may be increased. The Provincial Textile Industry Bureau is also preparing to organize before 1 May this year the cotton textile and printing and dyeing enterprises in the two cities of Shijiazhuang and Handan in combined test development of a group of polyester and cotton products suited to rural markets, and to go into villages to develop sales.

NEW, OLD HYBRID COTTON VARIETIES COMPARED

Shijiazhuang HEBEI RIBAO in Chinese 15 Apr 82 p 2

[Article by Su Shuangsuo [5685 7175 6956], Economic Crop Institute, Provincial Academy of Agricultural Sciences: "Disease-Resistant, High-Yield Yimaian No 2 Cotton"]

[Text] Yimian No 2 cotton (formerly termed Zhengding Zixuan No 3 or Zhengmian No 1) is a variety of cotton successfully bred by the Anxia Production Brigade's Science and Technology Team in Zhengding County, Hebei Province. Experiments and test plantings, as well as comparisons with Lumian No 1, which is currently winning prizes and being promoted thoughout the country, have attested to its leading position in many respects.

1. In fusarium yellow disease areas, yield are higher than for Lumian No 1. In 1978 and in 1980, these two varieties were involved at the same time in Huang He river basin area tests of varieties for resistance to fusarium yellow disease. At 12 different times and places over a period of 2 years, ginned cotton yields for Jimian No 2 averaged 157.3 jin, 18.6 jin more than for Lumian No 1. Six of these times and places were in Hebei Province where Jimian No 2 yields of ginned cotton averaged 174 jin per mu, an increase of 24.7 jin per mu of ginned cotton as compared with Lumian No 1. In addition, in fusarium yellow disease areas of Hebei Province the bumper yield properties and the early ripening properties of Jimian No 2 were also better than those of fusarium yellow disease resistant variety, Zhongmiansuo No 9 (formerly Zhong 399). At six different times and places over a 2 year period, average yields of ginned cotton were 8.8 jin more per mu than for Zhongmiansuo No 9. Before frost yields of ginned cotton were 6.8 jin more per mu (according to Huang He basin fusarium yellow disease resistant variety area data). Checks of two experiments this year by the Provincial Economic Crop Institute showed that the number of bolls per mu for Jimian No 2 were almost 4,000 more than for Zhongmiansuo No 9.

2. Increased yield potential is greater than for Lumian No 1. In area tests on conventional varieties conducted in the Huang He river basin, maximum yields for Jimian No 2 were 285.9 jin per mu of ginned cotton; for Lumian No 1, they were 264.9 jin (at Dali in Shaanxi Province in 1978). In nine of the experiments conducted at 35 different times and places over a 2 year period, Jimian No 2 exhibited ginned cotton yields of more than 200 jin per mu. The

same was true only three times for Lumian No 1. In area tests of fusarium yellow disease resistant varieties in the Huang He basin, maximum yields of ginned cotton for Jimian No 2 were 231.8 jin per mu; for Lumian No 1, they were 176.7 jin (in 1980 at Yongnian). In experiments conducted at 12 times and places over a 2 year period, Jimian No 2 produced yields of more than 200 jin per mu of ginned cotton in three, while Lumian No 1 had no yields of more than 200 jin at any test site. This shows the relatively greater increased yield potential of Jimian No 2 as compared with Lumian No 1. On the basis of test plantings over a several year period, leadership comrades at the Zhoujiazhuang Commune in Jin County believe the following: our commune, Jimian No 2 is superior to Lumian No 1. This variety does not lodge, does not degenerate early, and produces high yields.

3. Growth is better than for Lumian No 1. Because of the stronger growth of Jimian No 2, when grown on well manured ground, it is prone to vigorous growth that is difficult to manage. Secondly, in places where there was no yellow fusarium disease, it was relatively slow maturing. The opinion of communes and brigades in Hebei Province on the growing of Jimian No 2 is that though this is a high yield variety, it is not as easy to manage as Lumian No 1. When water and manure are increased during the mid-period, it is prone to vigorous growth. In area tests of conventional varieties conducted at 35 different times and places in the Huang He basin, pre-frost yields for Jimian No 2 averaged 29.7 jin per mu less than for Lumian No 1. However, in yellow fusarium disease resistant area tests conducted in the Huang He basin, its pre-frost ginned cotton yields were higher than for Lumian No 1. At several times and in several places in the Huang He basin, its yield averaged 3.6 jin higher, those in Hebei Province averaging 6.1 jin higher on six occasions in six places.

4. Fiber quality was virtually the same as for Lumian No 1. Results of fiber quality tests by the Huang He basin conventional varieties area testing organization showed quality of Jimian No 2 and Lumian No 1 to be virtually identical. Comprehensive appraisal of test spinning of 21-count yarn of the two varieties for 2 years showed both to be top quality second grade, their spinning qualities tending to be low.

5. Yields in areas free from disease were slightly lower than for Lumian No 1. In 1977 and 1978, Jimian No 2 and Lumiang No 1 were part of national area tests of conventional varieties conducted at the same time in the Huang He basin. Tests conducted at 35 different times and places over a 2 year period produced yields of ginned cotton averaging 154.4 jin for Jimian No 1, which was 4.2 jin per mu less than for Lumian No 1 (158.6 jin).

A summary of the foregoing shows Jimian No 2 to be no less a fine variety than Lumian No 1. In terms of increased yield potential, resistance to fusarium yellow disease and bumper yield qualities in yellow fusarium disease areas, it is superior to Lumian No 1. In Hebei province where a new situation of great development of cotton is underway, serious attention should be given this variety, and general methods should be adapted to local situations for the demonstration and promotion of this variety. In the course of demonstration and promotion, seeds should be dibbled to conserve the quantity of seeds used in order to enlarge the planted area with all possible speed.

PROVINCIAL PRICE POLICIES, PRACTICES PROPOUNDED

Shijiazhuang HEBEI RIBAO in Chinese 18 Apr 82 p 2

[Article: "Officer in Charge at Provincial Commodity Price Commission Answers Correspondent's Questions About Commodity Prices. Actual Increases in Peasant, Staff, and Employee Income in Hebei Province During the Past Several Years Have Been Greater Than Increases in Expenditures Resulting From Increases in Commodity Prices, Meaning An Increase in the Actual Standard of Living of the Masses"]

[Text] Recently the officer in charge at the Provincial Commodity Price Commission answered the correspondents questions about commodity prices as follows:

Question: What has been the situation during the past several years in Hebei Province as regards market retail price rises?

Answer: During the past few years, market retail prices in the province have risen somewhat. Statistics show that the province's overall social commodity retail price index rose 1.4 percent between 1978 and 1979, 5.3 percent between 1979 and 1980, and 2.1 percent between 1980 and 1981. The total rise during the 3 year period was nine percent for an annual incremental increase of 2.9 percent, virtual stability in market prices being maintained. So why is it that people always feel that the prices of goods have risen a great deal? This is because: (1) everyone is aware of the price rise for consumption goods that they regularly buy such as pork, beef and lamb, eggs, vegetables, fruits, tobacco, alcoholic beverages and aquatic products. Though the prices for some durable consumer goods such as television sets, wristwatches, chemical fiber cloth, stretch socks, electric meters, and electric fans have gone down, the price decline for some of them being very great; nevertheless, since people do not buy such items frequently, they remain unaware of the substantial drop in their prices. (2) Once negotiated prices for some agricultural products and liberalization of farmers' market trade occured, some things that could not be purchased in the past could now be bought at any time, making it easy for the masses. However, for some things, the price in collective markets is higher than the national list price, and people who buy things in farmers' markets have to pay more. (3) As a result of increase in standards of living, people have higher demands for food, clothing, and items used in daily life. Development of medium grade goods has also meant increased expenditures. (4) Some goods sold by plants, stores, and beverage stalls are low in quality and high in price, or have been short weighted. Use of such tactics constitutes a hidden price rise. Some people have also taken it upon themselves to raise prices or to enlarge the scope of negotiated price items, selling them at high prices. All these things make people feel that prices have risen a great deal.

Question: Have price rises hurt improvement in the people's standards of living?

Answer: Price rises have caused some increase in the living expenses of the masses, which has hurt the people's livelihood. However, for several years now peasant, staff and employee income has actually increased more than the increase in expenditures. Statistics show that in the period from 1979 to 1981 increases in procurement prices paid for agricultural products alone brought an increase in peasant earnings throughout the province of more than 2.6 billion yuan. After price rises have been subtracted from this total, each peasant still realized increased earnings of somewhat more than 41 yuan. As a result of increases in wages, payment of bonuses and employment of workers, family income of urban staff and workers greatly increased. Statistics show that in 1981 every staff and worker in the province averaged annual wage income of 742 yuan, a 159 yuan increase over the 583 yuan of 1978 for a 27.3 percent increase. The extent of increase in wages greatly exceeded the extent of increase in prices. Therefore, the actual standard of living of the masses also rose. Naturally, for households in which there was little employment of workers, increases in wages, or payment of bonuses, living standards were slightly impaired or may have even fallen for a small number of people. This situation will be gradually solved with development of production.

Question: What major decisions has the state made with regard to pricing policies during the past several years?

Answer: The major decisions taken during the past several years have been as follows: First was to increase procurement prices paid for agricultural products, with increased prices being paid for purchases in excesss of quotas for grain, cotton, and edible oil. Comparison of 1981 with 1978 shows overall procurement price levels for farm products throughout the province to have increased by 39.62 percent. Not only was this advantageous for peasants, but was also remarkably effective in development of industrial production, in providing an abundance of products to markets, and in improving the livelihood of people in cities.

Second, in the case of some consumer goods used in daily life for which prices were not fair, planned readjustments upward or downward were made. Since the second quarter of 1981, price hikes in the province have totaled more than 80 million yuan while price drops for the province have totaled more than 94 million yuan. Equitable upward or downward readjustments in the prices of goods have helped promote development of production, have helped expand circulation of commodities, and have played an active role in the coordinated development of the national economy. Some people suppose that stabilization of prices means one cannot carry out readjustment, or that prices can only go down but not up. Such notions do not take account of all factors, and do not fit in with the objective requirements of economic development. Maintenance of fundamental stability of market prices is our unswerving policy. While maintaining fundamental stability of commodity prices, we can readjust inequitable prices upward or downward. Stable prices are not frozen prices; there must be fundamental stability with equitable readjustments.

Third, in price management the former method whereby the setting of prices was done uniformly by the state alone has been broken. Instead multiple forms of pricing have been adopted including setting of prices by the state, negotiated prices and country fair trade prices. These fully embody the principles of taking the planned economy as primary and regulation by market mechanism as secondary. This way of doing things helps surmount the former excessive control and stifling control of prices, which impeded production and circulation of goods, and it helps enliven the economy. In this regard, because of lack of experiences, some problems still exist and steady improvements will be required in the course of practice.

Question: What actions have the party and the state taken to maintain the fundamental stability of market retail prices?

Answer: During the past several years, in order to maintain the virtual stability of market prices, the CCP Central Committee and State Council, the Provincial CCP Committee, and the Provincial People's Government have issued a series of major instructions strictly controlling commodity prices, restructuring negotiated prices, carrying out large sclae checks on commodity prices, and intensifying commodity price controls and supervisory work. In addition, procurement prices paid for agricultural products have been increased, but sale prices of basic necessities, which account for a very great proportion of the people's living expenses, have not been touched (e.g. for supply of fixed amounts of grain, edible oil, and cotton used for wadding). Losses resulting from such deals have been subsidized from national revenues. Although commensurate readjustment has been made in the sale price of some things (such as eight categories of non-staple and processed food made from pork, eggs, poultry, vegetables, and aquatic products), the state has instituted price subsidies for some industrial goods. Statistics for 1980 show price subsidies for the province to have totaled more than 1.2 billion yuan, accounting for about 30 percent of revenues. Price subsidies for grain and oil amounted to somewhat more than 400 million yuan. For example, actual procurement price paid for standard noodles averaged 0.25 yuan per jin, yet they were supplied at 0.185 yuan per jin. Corn flour was purchased at an average price of 0.17 yuan per jin and supplied at 0.116 yuan per jin. Average procurement prices paid for peanut oil was 1.42 yuan per jin, but it was supplied at 0.84 yuan per jin. Cotton subsidies amounted to more than 300 million yuan; price subsidies for non-staple foods amounted to more than 200 million yuan; price subsidies for coal purchased in markets for use in the daily life of the people amounted to more than 60 million yuan; and subsidies for soap and washing powder amounted to more than 4 million yuan. The state even subsidized the price of students' textbooks and red scarves. At the same time prices and fees paid for rent, for water and electricity, for train and bus tickets were strictly controlled and straightened out so that, insofar as possible, expenditures by the masses would not be increased.

PROXIMITY TO CITIES EXPLOITED TO DIVERSIFY LOCAL ECONOMY

Shijiazhuang HEBEI RIBAO in Chinese 2 Apr 82 p 2

[Article by Shi Tongwen [0670 0681 2429] and Jia Yujun [6328 3768 0689]: "Make the Most of Local Advantages Through Development of Economic Diversification. Langfang Prefecture's Income Last Year From Economic Diversification Amounted to More Than 60 Percent of Total Rural Income"]

[Text] By actively making the most of its advantage in being near the two cities of Beijing and Tianjin, Langfang Prefecture has won outstanding economic results from its vigourous development of economically diversified production. In 1981, the prefecture's income from commune and brigade economic diversification amounted to 524.6 million yuan, more than 60 percent of its total rural economic income and a 37 percent increase over 1978.

In order to take full advantage of its location close to the two cities of Beijing and Tianjin, Langfang Prefecture was at great pains in the development of its economic diversification to organize production to meet market needs in the two cities. In view of the serious shortages of fresh vegetables, melons, and fruits in the two cities every year in the past, they energetically increased output of fresh vegetables, melons, and fruits and took the initiative in doing a good job of transportation and supply work. In 1981 the prefecture provided Beijing and Tianjin markets with more than 400 million jin of fresh watermelons and vegetables of various kinds, earning more than 22 million yuan thereby. Both Beijing and Tainjin were fairly short of building materials, so Sanhe, Xianghe, and Dacheng counties in Langfang Prefecture used local resources to produce construction materials such as cement, lime, crushed stone, and bricks, which enjoyed a very good market. Now small commune and brigade operated building materials enterprises in the prefecture number more than 270, employing more than 20,000 people. Many of the communes and brigades in the prefecture have used local agricultural products to do large-scale processing of small food items. For example, Chengguan Commune in Dacheng County, a county that produces prodigious quantities of mung beans and in which the masses know the techniques for processing mung bean pudding, organized the masses to make mung bean pudding. Within a year's time, the commune was operating 67 mung bean pudding processing plants that employed nearly 1,000 people. Between January and October last year, earnings were 2.1 million yuan, more than 50 percent of the earnings of all commune and brigade enterprises in the prefecture.

Langfang Prefecture also used various methods of association to actively bring into the prefecture funds, skills, and enterpirse management experiences from Beijing and Tianjin. During the past 2 years, it has developed in cooperation with the two cities a total of more than 1,700 joint economic operations including just stock ventures, compensatory trade, and processing of materials brought in from elsewhere. Last year, gross earnings totaled more than 31 million yuan for profits of more than 14 million yuan.

KEY MEASURES TO COMBAT DROUGHT REITERATED

Shijiazhuang HEBEI RIBAO in Chinese 28 Mar 82 pp 1, 2

[Article: "Strengthen Leadership; Give Firm Attention to Crucial Measures; Thoroughgoingly Carry Out "Double Assurances" in Combat Against Drought. Officer-in-Charge at Provincial Flood Prevention and Drought Combat Command Expresses Views to the Correspondent on How To Carry Out the Struggle Against Drought Now"]

[Text] Recently an officer-in-charge at the Provincial Flood Prevention and Drought Combat Command expressed views to this newspaper's correspondent about the present drought situation in the province and about how to launch struggle against drought. He said the following.

The drought situation in Hebei Province is now extremely serious. Since the lunar new year, rain and snow have continued scant. During the last 10 days of February there were two light to moderate rainfalls, and in prefectures to the south of Baoding and Hengshui, there was somewhat more. At first some amelioration of the drought seemed possible, but because of the long drought and the recent steady climb in temperatures, soil moisture has evaporated quickly. Even in places with faily large rainfall, basic soil moisture has not been re-established. Measurements made at various places show soil moisture content at a depth of 10 centimeters to be 13 to 14 percent, and at a depth of 20 centimeters to be only 9 to 11 percent. The area of the province lacking sufficient soil moisture now covers more than 59 million mu. Unless a soaking rain soon falls, it will not be possible to sow on time on an unplowed field area of almost 20 million mu. As a result of consecutive years of drought, sources of irrigation water have been greatly reduced. The quantity of water available for use in the province's large and medium size reservoirs is now less than one-fourth the amount available in ordinary years. The groud water table continues to decline precipitously. In mountain areas and on the plains, the number of production teams experiencing difficulties with drinking water for people and livestock is steadily increasing. Some teams have to haul drinking water from as far away as 90 li. According to forecasts from meteorological units, rainfall during April will continue to be less than in normal years.

Faced with serious drought, all jurisdictions have taken vigorous action to launch a struggle of "one combat and double assurance." Following two telephone conferences by the Provincial CCP Committee and the provincial government, counties and prefectures have convened different kinds of conferences of implementation in which were put forward specific actions and requirements, and a large number of cadres were sent into the front line of combat against drought. According to incomplete statistics, a total of somewhat more than 22,300 cadres were sent into the front lines of combat against drought everywhere. All jurisdictions have given strict attention to institution of pump well management responsibility systems. More than 300,000 of the 480,000 pump wells that have been equipped in the province have established pump well management responsibility systems. This amounts to 65 percent of all equipped pump wells. All jurisdictions have also stirred the masses to open up new water sources. As of the end of February, the province's newly opened pump wells, equipped pump wells, and delapidated wells restored to operation numbered more than for the same period last year. In addition, some small water conservancy projects that can be used to combat drought during the present year requiring little investment and showing quick results have been built. These all greatly increase capabilities to combat drought. Spring irrigation has been done on 10.65 million mu of wheatfields and as yet unplowed fields, 3.05 million mu more than was watered during the same period last year. In addition, strict attention has been given the hoeing and raking of wheatfields and the harrowing of the land to conserve soil moisture.

In order to have a fairly good summer harvest and complete spring sowing tasks on time, all jurisdictions should give attention to the following tasks in their combat against drought.

First is strengthening of leadership of drought combat work. Party and government units at all levels are to transfer large numbers of cadres to the front line of combat against drought, and leadership cadres at all levels are particularly to further change their work style, going to places with great hardships and going to places where life is arduous to help solve practical problems in the fight against drought. Cadres who go down to the countryside are to direct their attentions first of all to the building of grassroots teams, and to the reorganization of the small number of moribund or semi-moribund leadership teams in order to be able to concretely organize leadership of the masses for combat against drought.

Second, when perfecting agricultural production responsibility systems, pump well management responsibility systems must be put into effect so that full benefits may be derived from existing pump wells. A look at the present situation shows that 35 percent of pump wells lack systems of responsibility, and at a substantial number of pump wells no one is in charge; water is available, but the fields cannot be watered. This problem must attract a high degree of attention on the part of all jurisdictions. The establishment and perfection of pump well management responsibility systems must be taken in hand as an important matter in the task of combating drought this spring, forces being concentrated in time for diligent attention to implementation, well by well, for resolute solution of the problem of pump wells with no one in charge, and having wells but not being able to water the fields. No matter the form of agricultural responsibility system instituted, pump wells must be under centralized management of production brigades or production teams, and where pump wells and pumping machines have been parceled out, they must be resolutely recovered. Those who steal pumping machines or damage pump wells and other water conservancy facilities are to be promptly and severely dealt with.

Third, water sources are to be expanded to increase capabilities to combat drought. Places having requisite conditions are to vigorously seek fresh water by digging shallow wells, individual households or a collection of households digging the wells, the method to be used being ownership, management, and use belonging to the diggers to encourage the masses to sink pump wells. Pump wells that have not yet been equipped should be equipped, and crumbling or abandoned wells put back into operation. The masses should be aroused to dig open old brick wells, to open hand pump vacuum wells, and to dig ditches and pits. Places having water above ground that can be used should manage and use it well so that it can play a full role in combat against drought. In addition, full use should be made of urban waste water and mining area effluent, every available means being used to expand sources of water and increase capabilities to combat drought.

Fourth, is diligent scientific use of water, planned use of water, and conservation in use of water. The most important actions to be taken are sealing leaks in ridged ditches from pump wells, leveling fields, irrigating small plots, combining the flow from many wells, watering with a combination of brackish and fresh water, rolling of unplowed fields before watering them, and active development of spray irrigation, conserving water resources to the maximum extent possible while expanding the area watered. In addition, a good job of harrowing and rolling should be done to conserve soil moisture, and wheatfields should be hoed and raked to reduce moisture evaporation. In places where spring sowing tasks are heavy and water resources insufficient, preparations should be made to dibble seeds to combat drought in an effort to plant on time. In low-lying areas where water resources cannot be assured, general methods should be adapted to local situations in a readjustment of crop patterns, with greater planting of drought-resistant, waterlogging-resistant, and alkaline-resistant crops.

Fifth, attention should be given to conservation of petroleum and electricity. Right now petroleum products and electricity are in seriously short supply. This is particularly true of diesel oil. Counties, communes, and brigades are to assign people to management of diesel oil, allocating oil for use on the basis of irrigated area criteria, and supplying oil on the basis of the pace of watering. At the same time effective action should be taken to plug diesel oil leaks and, when necessary, to restrict other uses of oil to assure needs for combating drought. In the case of pump wells that use electricity, the masses should be organized to the maximum extent possible to water fields during nighttime hours of low demand.

Sixth is carrying forward a spirit of self reliance. There are limits to support funds that the state can provide to combat drought; mostly the strength of the masses will have to be relied upon, and there will have to be conscientious organization. Expense funds to combat drought handed down by the province should be well managed and well used. Funds to combat drought must be used where they will do the most good. They should be used to provide timely help, going mostly to sustain communes and brigades suffering economic hardships, making them play a role as rapidly as possible.

Seventh, all trades and industries must vigorously support combat against drought. Commercial units should make plans for allocation and supply of diesel and engine oil; electricity units are to solve problems in use of electricity to combat drought; supply and marketing units are to assure prompt supply of materials needed to sink wells; farm machinery units are to organize technicians to go into the countryside to help commune and brigade maintenance of drainage and irrigation equipment; and banking units are to promptly issue loans to support communes and brigades in combat against drought.

We believe that with the strengthening of leadership and the mobilization of the people throughout the province to surmount paralysis and the trusting to blind luck, and by building confidence, victory can surely be won in the struggle against drought.

CONSERVATION OF AGRICULTURAL USE OF WATER EMPHASIZED

Shijiazhuang HEBEI RIBAO in Chinese 13 Feb 82 p 2

[Article by the Science Coordination Office of the Shijiazhuang Prefecture: "Conserve Agricultural Use of Water, Restore Balance Between Extraction and Replenishment"]

[Text] At present, anarchy exists in the use of water for agricultural irrigation. Each unit reigns over its own resource and each unit extracts water without restraint. This has created great destruction of the resources of water supply. Shijiazhuang Prefecture always had rich underground water resources, and it believed that such resources were inexhaustible, so no attention was given to retaining and storing water sources and conserving the use of water. In recent years, extraction of underground water has not been limited and there have been no quotas for the use of water. Because of massive extraction, the balance between extraction and replenishment of underground water has been destroyed, and the level of the water reserves has decreased year after year. At the beginning of the 1960's, the level of underground water was not deeper than 4 meters. Now, the level has reached more than 10 meters deep, and "funnel" areas of varying degrees have emerged in Zhao County, Jin County, Gaocheng, and Zhengding. The large-scale drop in underground water has forced the abandonment of over 30,000 mechanized wells. Less than 20 percent of the rest of the mechanized wells are able to produce full wells of water. The yield of agricultural production has been reduced in many places, and in some places there have not been any harvests. Take wheat as an example: last year, 270,000 mu of wheat fields did not produce a harvest because of a lack of water and on 400,000 mu there was a reduced yield, so there was a shortage of over 100 million jin in the yield of wheat. Last spring, 390,000 mu of spring sown fields became summer sown fields because of drought and little rain. After the underground water level dropped, the distance for pumping water to the surface increased, and this raised the consumption of fuel and power. Some localities also had to purchase new water lifting equipment. This increased the cost of agriculture and reduced the income of farmers. Therefore, the problem of scientific exploration and utilization of water resources has become more than simply an academic problem: it is an acute, real problem affecting the life of the people and the nation that needs to be solved urgently. At present, the water sources in some localities are deficient. This has already brought about serious loss to the development of the national economy. This lesson must be learned.

The greatest hindrance to conservation of water at present is the widely existing emphasis on developing water sources while neglecting conservation of water flow, the attention to immediate benefits and the neglect of long-term benefits, and the emphasis on determining supply based on need and silence in determining need based on supply. To solve these problems, recognition of the crisis in water resources by the leadership at each level must be increased. At present, the conflict between supply and demand on water resources must be eased. We must manage the following aspects in a key way. First, we must draw up plans and strengthen management. We must zone the regions for water conservancy well, and establish concrete measures and methods for scientific use of water. We must implement various forms of the responsibility system to closely combine conservation of water with the economic benefits of the departments and the individual. Second, we must conserve water via many channels. Measures must be implemented to prevent leakage in water conservancy projects and main waterways by suiting measures to local circumstances to improve the effective utilization coefficient of canal systems. We must retain water and soil well, bank soil fertility, thicken the soil layer, level the land, strengthen raking, and change the unscientific method of using irrigation to replace tilling. We must develop the good tradition of fine tilling and careful planting, change large ridges into small ridges and long ditches to short ditches. We must exert efforts to explore the pattern of the need for water of different crops and irrigate scientifically at the appropriate time and in appropriate amounts. Third, we must rationally exploit water sources and open up broad water sources. We must establish the concept that the entire prefecture is one chessboard in agricultural use of water, and all kinds of water sources such as canals, wells, reservoirs and ponds must be uniformly controlled and used. We must fully utilize various kinds of abandoned water sources and actively develop back irrigation. We must develop the gain of groups of wells so that deep, medium and shallow wells can be combined. We must strengthen the study and utilization of alkaline water, polluted water and water in the soil so that their function can be developed for production.

PROVINCIAL GOVERNMENT INSTRUCTS ALL CITIZENS TO PLANT TREES

Shijiazhuang HEBEI RIBAO in Chinese 11 Feb 82 p 1

[Notice issued by the Hebei People's Government on 9 February 1982: "Notice on Tree Planting Duties by All Citizens, Hebei Provincial People's Government (No Other Circulars)"]

[Text] To all regional administrative offices, all city and county people's governments (revolutionary committees), all departments of the provincial government:

The "Decision Concerning the Duties of All Citizens in the Tree Planting Movement" passed by the Fourth Session of the Fifth National People's Congress pointed out: "All citizens of the People's Republic of China reaching 11 years or age, except for the old, the infirm, the sick and the handicapped, must suit measures to local circumstances, and each person has the duty of planting three to five trees a year, or cultivating saplings, managing and protecting trees and fulfilling other greening duties equivalent to the amount of labor in tree planting." To implement the movement of the voluntary tree planting duty by all citizens broadly, profoundly and persistently in all provinces, cities and villages, and to combine the notice with the actual situation in our province, the following notice is issued:

I. The voluntary tree planting movement by all citizens is an important strategic measure to green the motherland, to control mountains and rivers, and to maintain and improve the ecological environment. It will greatly promote the beautification of the motherland stimulate the wealth of the nation, bring prosperity to the nationalities and civilization to society. Each locality and each unit must conscientiously study and propagate in a visible way the "decision" concerning voluntary tree planting as passed by the Fourth Session of the Fifth People's Congress so that every family knows and everyone understands and every citizen can conscientiously participate in the voluntary tree planting movement.

II. Each locality, city, county, each commune and each brigade in farm villages, each agency, plant, mine, school and business unit must plan voluntary tree planting well. The duty of planting three to five trees by each person must be implemented at each basic level and by each individual and in each plot of land according to each sector and each unit. Communes and brigades in farm villages must first afforest expanses of land suitable for forestation, build forest networks in farmland, and plant trees in land surrounding villages and towns. Communes and brigades in mountain regions must organize commune members to complete the duties of greening and forestation of private mountains and contracted mountain land for forestation which are their personal responsibilities while the communes and brigades complete the voluntary duties of planting trees. Cities must carry out the work of greening public land, greening scenic attractions and ancient ruins and land along streets. Offices, schools, troop units, factories and mines must first carry out the work of greening their own units. Voluntary tree planting should first be arranged for nearby state-run timber farms, commune and brigade timber farms or state-run cooperative forest farms.

III. Sapling cultivation must be carried out well. Each locality must exert efforts to manage the present state-run nurseries, nurseries in gardens and forests, nurseries for railroads, and commune and brigade nurseries. At the same time, a definite area of land and specialized personnel must be arranged to expand and build new sapling bases and cultivate superior quality and healthy saplings. City and town offices, factories and mines, troops, schools and such units must be encouraged to build their own nurseries. Units that do not have conditions for establishing nurseries can sign contracts with nurseries for sapling supplies and for ordering supplies of saplings. State-run timber farms and state-run nurseries must all actively produce commercial saplings for voluntary tree planting. Communes and brigades in farm villages that have contracted work to the families and production to the families must establish the area for sapling cultivation according to the size of the task of forestation and appropriate sufficient land for sapling cultivation. The investment in saplings needed for voluntary tree planting by each locality and each unit should generally be solved by the units holding rights to forest timber themselves. The financial offices of the local governments at each level must allocate a definite sum each year to support voluntary tree planting.

IV. The task of voluntary tree planting must include attention to practical results and guarantee quality and quantity in completing the task. Measures must be suited to local circumstances, trees suitable to the locality must be planted, and there must not be arbitrary uniformity. Technical knowledge in greening and tree planting must be popularized, technical rules for voluntary tree planting must be established, and technical backbone forces must be trained and technical guidance strengthened so that every tree planted will live. Management and protection of forests must be strengthened, the responsibility system of protecting forests must be soundly established, and special teams, special groups and special persons must be assigned to manage and protect the trees. Felling and renewing forests must be carried out according to regulations and must be approved. No unit and no individual is allowed to fell trees at will or to destroy trees.

V. Leadership in voluntary tree planting must be concretely strengthened. Comrade Li Erzhong [2621 1422 6850] heads the Provincial Greening Committee as chief commissioner. Each level must establish a greening committee to be headed by a leading comrade of the local government and to consist of responsible comrades of related departments and civilian organizations who will be uniformly responsible for the greening of the locality and for organizing leadership in voluntary tree planting. This year's voluntary tree planting work must be actively started and must progress steadily. All localities with mature conditions, such as localities with sufficient saplings, localities that have plans and that have technical training, must launch the tree planting movement on an overall basis. Localities with immature conditions must actively work well to create appropriate conditions. We must adhere to the principle of doing the easy tasks first and the difficult tasks later and develop a group of key localities and units for voluntary tree planting to summarize experience, to develop the point to lead the rest, and to push forward the development of voluntary tree planting. The greening committee at each level must inspect the progress in voluntary tree planting once a year in the fall and must report to the people's government at the same level. Those with outstanding achievements should be praised and rewarded. Units or individuals who do not carry out the duties without reason should be subjected to criticism and education or economic sanction.

Hebei Provincial People's Government

STRENGTHENING PUMP WELL RESPONSIBILITY SYSTEM URGED

Questions on System Answered

Shijiazhuang HEBEI RIBAO in Chinese 22 Mar 82 p 2

[Text] Question: Right now the drought situation is serious throughout the province. How can the full benefits of pump wells be brought into play to combat the drought?

Answer: Over the years Hebei Province has built almost 500,000 fully equipped pump wells to water an area of more than 40 million mu, which is more than 70 percent of theprovince's total irrigated area. Making full use of the benefits pump wells can provide is a major assurance for victory against drought. Moreover, the priority task of the moment in making full use of benefits pump wells can provide is the building and perfecting of pump well management organizations, assignment of management personnel, and formulation of management systems. A look at the present situation shows that results differ greatly from good and bad management of pump wells. In Yongnian County, after the Tongtou Production Brigade instituted a pump well management responsibility system, individual well benefits increased from the former 57 mu to 107 mu, and costs per mu per time watered fell from 1.03 yuan to 0.48 yuan. Diesel fuel consumption per mu per time dropped from 4.1 jin to 2.[illegible] jin. Additionally, institution of responsibility systems also paid off in lengthening the useful life of pump wells and their equipment. Therefore, in today's situation of severe drought and a lack of water sources, in perfecting their systems of responsibility every jurisdiction should first of all establish and perfect pump well management responsibility systems.

Question: What is the present situation in Hebei Province regarding pump well management responsibility systems?

Answer: Along with the consolidation and perfection of agricultural production responsibility systems, numerous places have devoted attention to implementation pump well management responsibility systems. In terms of the province as a whole, responsibility systems that have been handled rather well number about 50 percent of the total. The other half have not been handled well, and more than 10 percent of these have no one in charge. Irrigating the fields is very difficult in these, and fights over wells, fights over machinery, and even damage to the pump wells and machinery has taken place. This is a very large problem to which all echelons of leadership must devote a high degree of serious attention and rapidly take action to effect a change.

Question: What forms of pump well management responsibility systems currently exist in Hebei Province?

Answer: Right now Hebei Province's pump well management responsibility systems are mainly of four different kinds: One kind is centralized management by production brigades or production teams, whereby the actual task of managing wells and using wells is contracted to specialized teams. A second kind uses well teams in the practice of a specialized contracting responsibility system. The specific method used is to fix field watering tasks on the basis of pump well water output and condition of the pumping equipment, assigning pump operators or field plot hands control over the watering of fields. A third kind is contracting pump wells or pumps to individual commune members or peasant households, making contracts by the quarter or by the year, some of them providing for complete assignment of responsibility for expenses, some of them contracting costs per mu per time, the time of watering being set for each mu, and fees collected according to the amount of time, the plots being looked after by the households. The fourth kind is a responsibility system whereby land supports the well. In this system, in addition to looking after the well, the pump operator is assigned a certain amount of land around the well for development of economic diversification. Income from use of this land provides compensation to the pump operator. Recently some places have tried setting up pump well companies, collecting fees according to fixed standards from households whose land is watered.

Question: What problems have to be given attention and solved in the establishment and perfection of pump well management responsibility systems?

Answer: Experiences of some communes and brigades that have managed pump wells properly show that the following must be done in order to do this work right: 1) Production brigades and production teams have to have cadres specifically responsible for this work, and they must steadily summarize experiences and solve existing problems. 2) For each pump well one or two people who are enthusiastic about the collective, who have a strong sense of responsibility, and who have certain cultural and technical attainments should be selected, and relative stability should be maintained in such assignments. 3) Good solution to problems of responsibility, rights, and benefits of pump operators. There should be a defined system of responsibility for pump operators. Those who fulfill tasks well should be commended and given rewards; those who do not fulfill their tasks or manage badly should be criticized and indoctrinated. 4) Solution to the relationship between the "centralized" and the "contracted." Pump wells are collective property that should certainly be maintained under centralized management for centralized use. Places that practice "double contracting" responsibility systems should particularly not dismantle pump wells and equipment.

Question: At this time when the drought is serious in Hebei Province, what is to be done about places where no one is in charge of pump wells and where watering cannot be done from wells?

Answer: These places have to take firmly in hand the establishment of pump well responsibility systems. If time is pressing and they cannot set up such systems at once, they can appoint people responsible for them, and management methods may be worked out gradually from the simple to the complex. It is also possible for production brigade or production team cadres to take charge of pump wells, resolutely surmounting the situation of having wells but not being able to do watering. In addition to this, it is necessary to resolutely halt the destruction of pump wells and the private dividing up of machine pumping equipment. All pump wells or machinery that belong to the collective and have been divided up must be handed back. Whatever had been destroyed must be paid for. Those who have illegally occupied or destroyed state or collectively owned water conservancy projects or facilities are to be criticized, indoctrinated, and required to pay compensation for damages in not so serious cases. Serious cases should be punished according to the law.

Provincial Notice Issued

Shijiazhuang HEBEI RIBAO in Chinese 31 Mar 82 p 1

[Text] Recently the Provincial CCP Committee Rural Work Department and the Provincial Water Conservancy Department jointly issued a "Notice on the Establishment and Perfection of Pump Well Management Responsibility Systems," which requires all jurisdictions to treat as a matter of urgency the establishment and perfection of pump well responsibility systems in the perfection of agricultural production systems of responsibility, and as a key measure of "double assurance" in combat against drought, taking it firmly and well in hand.

The notice said that the nearly 500,000 fully equipped pump wells in the province are a major result of the province's water conservancy construction, are precious wealth accumulated by the arduous labor of cadres and masses over a period of many years, and are a major guarantee for combating drought to promote increases in agricultural production. Since the Third Plenary Session of the 11th Party Central Committee, many communes and brigades have established pump well management responsibility systems, which have played an outstanding role in improving irrigation benefits and lowering irrigation costs. However, pump well responsibility systems have not been set up in some communes and brigades, or else, though set up, they are far from complete. In some brigades that practice "double contracting" pump wells are not under centralized management and there is no responsibility system. In some there are pumps but no watering is done; there is fighting over the wells and the pumps, or even destruction of pump wells and the selling off of machinery to the serious impairment of benefits from pump wells. All jurisdictions must direct a high degree of serious attention to this matter, take effective action, and diligently solve the problem.

The notice required all jurisdictions while implementing the spirit of the national rural work conference to make the establishment and perfection of pump well responsibility systems an urgent task in perfection of agricultural production systems of responsibilities, and to make it a key measure in doing a good job on the "one resist and double guarantees," diligent attention being given it production team by production team and well by well. Where such responsibility systems have been established, experiences should be summarized and further perfection done. No matter the form of responsibility system established, it should conform to the agricultural responsibility system. There should be adaptation of general methods to local situations, and adaptation of general methods to individual production teams, permitting diversity, no "arbitrary uniformity" being practiced. No matter the form of agricultural production system of responsibility practiced, pump wells must be under the centralized management of production brigades or production teams. No matter the form of pump well responsibility system, commune members should be aroused to democratic discussion and decision. For each well, one or two people who love the collective, who have a strong sense of responsibility, and who have certain technical attainments should be assigned as pump operators, and there should be relatively little change in such assignments. Pump operators' rights, responsibilities and benefits should be clearly set, and centralized management and centralized watering should be maintained. In brigades in which pump well management systems cannot be established for the time being, a production brigade or production team cadre should be assigned to pump well management and to the organization of service, so that the wells can play a role in combat against drought.

The notice stressed that all levels of CCP committees, government, and rural work units must strengthen leadership over the establishment and perfection of pump well management responsibility systems, take centralized action, and conscientiously supervise and promote check-ups. All levels of water conservancy units are to conscientiously take in hand pump well management as an important task, and help communes and brigades in concrete ways to establish and perfect systems of responsibility, solving existing problems. Water conservancy cadres at all levels are to gradually establish personal responsibility systems, making explicit reward and punishment methods. Communes are to designate one cadre responsible for taking charge of pump well management and all water conservancy work, and when there are difficulties in the assignment of commune personnel, they may be transferred from county water conservancy departments to solve the problem. Production brigades and production teams are to have a single cadre take charge of water conservancy work. All places having wells and pumps that are not being put to use are to investigate leadership responsibility. Dismantling, destruction, or damage to pump wells and other water conservancy facilities is to be resolutely corrected. Equipment distributed among households must be taken back. What has been destroyed must be restored as a matter of urgency. In cases of illegal occupation or damaging of state or collectively owned water conservancy project facilities, investigation of responsibility is to be carried out and restitution for damages paid, economic penalties being imposed as required according to varying circumstances. In cases where serious damage has been done, criminal responsibility is to be fixed.

HUNAN

NEED FOR SKILLED SEED PRODUCTION TECHNICIANS UNDERSCORED

Beijing RENMIN RIBAO in Chinese 20 Apr 82 p 2

[Article by Correspondent Yang Shanqing [2799 0810 3237]: "Improve Hybrid Rice Seed Production Work"]

[Text] Recently the correspondent learned from agricultural units in Hunan Province that some places suppose that hybrid rice seed production has passed all tests and, as a result, new problems that have appeared in seed production following institution of responsibility systems have yet to be promptly studied and solved. Consequently, the number of units producing seeds has increased but technical guidance has not kept up; yields have dropped; quality has declined; and accidents involving mis-matching and misuse of seeds have occurred. Statistics show that last year in Hunan Province, seeds were mis-matched for 14,000 mu of late rice in seven counties, resulting in a more than 8 million jin reduction in grain output.

In view of this situation, Hunan Province convened a conference of seed company managers from all prefectures, municipalities, and some counties to summarize the lessons of experience in hybrid rice seed production work. The composite view of the group is that seed production now must give attention to the following several improvements.

1. Purification and rejuvenation of the "three line" (sterile line, sterile-free line, and restorer line) parent pairs. Only when the "three line" parent pairs are of a high degree of purity can a fine variety hybrid generation be produced to make use of increased yield heteroses and win bumper harvests in open fields. Consequently all prefectures are to provide financial, material, and technical resources, strengthen cooperation among individual units, and select stock farms having the best conditions for the breeding of parent pairs. Seed companies are, without exception, to be in charge of supplying parent pairs of the "three lines." Production, storage, and release must strictly follow technical control regulations to insure quality.

2. Adherence to centralized continuous tract seed production. Experience has shown that only through the organization by counties of continuous tract seed production can manpower, financial, and material resources be concentrated for

use, and leadership be better strengthened to provide good technical guidance and prevent mix-ups among hybrids to obtain high yields, superior quality, and low costs. Formerly Suining County dispersed its seed production, and yields averaged only 60 jin per mu, with more than 20 percent of seeds being mis-hybridized. In 1979, they began to centralize seed production on continuous tracts and yields per unit of area climbed year after year. By 1981, yields were 215 jin per mu, and purity of 91.2 percent of the seeds met first grade standards. As a result of dispersed seed production of late crop hybrid rice on more than 3,000 mu in Chaling County last year, varieties were mismatched and not a single kernel was harvested. From this it may be seen that dispersed seed production must be resolutely corrected and continuous tract seed production energetically organized.

3. Establishment of a Skilled Technical Corps. The experiences of some advanced units show that for every 1,000 to 1,500 mu of seed production area, one technical cadre has to be assigned. For every 100 to 150 mu, one peasant technician has to be assigned. Comrades who are professionally competent and have a strong sense of responsibility are to be chosen as technical personnel, and they are to be given strict training with no improvisations. A responsibility system of four fixeds and one reward (fixed seed production area, fixed seed yields per unit of area, fixed seed quality, fixed wage compensation, and reward for overfulfillment) is to be instituted for seed production technicians so as to fully arouse their enthusiasm to strive to do a good job of seed production work.

DITCHING TECHNIQUES USED TO RELIEVE WHEATFIELD WETNESS

Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Apr 82 p 2

[Article: "Huainan Prefecture Solves Wheatfield Damage Caused by Wetness For Rapid Development of Wheat, Barley and Naked Barley Production"]

[Text] Jiangsu Province's Huainan region is crisscrossed by streams and harbors, and has numerous lakes and marshes. The ground water table is high and quantity of rainfall is great. For many years this region's 25 million mu of wheatfields have sustained damage from wetness, which has impaired high and consistent yields. In order to effectively prevent wetness damage to wheat, barley, and naked barley, the region's agricultural science and technology promotion personnel worked together with the farflung cadres and masses on experiments and demonstrations supported by agricultural levels at all levels in the province and prefectures, promoting use over a wide area of a series of ditching techniques for draining water and lowering the wetness of wheatfields. Today a combination of open and underground ditches and of ditches in the fields and outside the fields has been formed throughout the province. Building of ditches to drain away water has been linked to control of the water level in inland streams in an integrated technical system for comprehensive control of damage from wetness. Specifications attained have been "for every wheat field, discharge of water from both ends; three ditches linked to form a whole; free and clear all around, open and hidden ditches in combination, and the inside and outside of fields linked together." This has effectively solved the problem of damage to wheatfields resulting from wetness, and has promoted rapid development of wheat, barley, and naked barley growing throughout the province. In Suzhou, Zhenjiang, Yangzhou, and Nantong prefectures, and in Nanjing municipality, the wheat growing area of the Huainan region, wheat, barley, and naked barley yields per unit of area have steadily climbed. Between 1978 and 1980, wheat yields were 472 jin per mu, a 43.2 percent increase over the early 1970's. Figuring an 80 jin per mu increase in the wheatfield area equipped with the three kinds of ditches, for the province as a whole the increase in wheat, barley, and naked barley harvest in the 3 year period from 1979 to 1981 was more than 5.3 billion jin.

PROVINCIAL LIVE HOG PRODUCTION BEGINS RECOVERY

Beijing RENMIN RIBAO in Chinese 7 Apr 82 p 1

[Article: "Taking Timely Measures Aimed at the New Situation, Jiangsu Province Live Hog Production Begins Recovery"]

[Texg] Measures taken by Jiangsu Province to develop live hog production has produced results. Since the beginning of this year, farm villages of the whole province have basically turned around the situation of persistent decline in the number of sows in pens and the slackening sales of young pigs. A recovery trend in the production of live hogs has emerged. According to statistics up to the end of February, the number of sows in pens throughout the province (including reserve sows) has approached the level of the same period last year. From January to February, the number of young pigs throughout the province increased 1.5 million head from the same period last year. In February, the number of live hogs throughout the province in pens increased by 150,000 head over January, and the number in March showed further increase over February.

Jiangsu Province is one of our nation's key regions producing commercial hogs. In recent years, 1,700 to 1,800 head of fattened hogs were submitted and sold to the state each year. Last year, the number of fattened hogs and sows dropped, and the sale of young hogs throughout the province has slackened since the second quarter of last year during the course of perfecting the agricultural production responsibility system at the localities. The responsibility system for raising hogs was not implemented in time and some measures carried out by the localities to encourage commune members to raise hogs were not conscientiously implemented.

To change this situation, the Provincial Committee of the Chinese Communist Party in Jiangsu Province and the provincial people's government conscientiously analyzed the situation of raising hogs and live hog production throughout the province at the province-wide farm village work conference and the province-wide agricultural conference, and they established several measures to stabilize and develop live hog production aimed at the new situation and the new problems that have emerged in live hog production.

--The policies of assigned raising, assigned procurement and rewards for sale of live hogs were implemented. The assigned procurement task and the tasks of procuring food grains, cotton, oil were simultaneously issued, and they were implemented at each level in the counties and communes. The commercial departments signed contracts with production teams and commune members.

--The collective arranged for the feed grains needed by commune members to raise hogs. The production team allocated and kept the feed grains uniformly and distributed them uniformly. Whoever raised hogs received feed grains.

--Each locality implemented some economic subsidies according to the actual situation. For example, some production teams subsidized 1 jiao or one work point for selling 1 jin of fattened pork. In other cases, the province subsidized 5 jiao, and the county, the commune and the brigade each subsidized 5 jiao for each piglet born by a sow of the collective.

WORK ON ROOT NODULE BACTERIAL MANURE HIGHLIGHTED

Beijing GUANGMING RIBAO in Chinese 21 Apr 82 p 2

[Article by Wang Desheng [3769 1795 3932]: "Effectiveness Outstanding in Research and Promotion of Root Nodule Bacteria Bacterial Manure by Liaoning Provincial Academy of Agricultural Science's Institute of Pedology and Fertilizer Assistant Researcher, Ma Linxiang [7456 7792 4382]"]

[Text] For 4 consecutive years, Ma Linxiang, assistant researcher in the Institute of Pedology and Fertilizer of the Liaoning Provincial Academy of Agricultural Sciences has carried on the study and promotion of soybean and peanut root nodule bacteria bacterial fertilizer, winning outstanding results.

Back in 1966, Ma Linxiang began the study of root nodule bacteria bacterial fertilizer for pulses and other crops, including soybeans, peanuts, peas and clover. Through arduous and intensive research, he was able to painstakingly sift from among 33 root nodule bacterial strains five highly effective bacterial strains that were suited to different regions, different soils, different crops, and different varieties in Liaoning Province. In December 1981, these underwent appraisal and approval by leadership units concerned in the province, and by national experts in the same field who agreed that this scientific research accomplishment met rather advanced domestic standards. Now it has been provided to four root nodule bacteria preparation plants inside and outside the province as fine variety bacterial strains. Ma Linxiang gave up a great many holidays and leave periods to go into individual cities (prefectures), counties (regions), communes (farms), and brigades. He traversed the 44 bacterial manure cooperative network sites all over Liaoning Province, both conducting investigation and research and carrying out technical promotion, and in the cities and counties of Shenyang, Jinzhou, Heishan, Xinjin, and Benqi, he gave speeches on eight different occasions to technical training classes, experience exchange meetings, and academic discussion meetings. He also trained more than 600 mainstay cadres for the promotion of bacterial fertilizer. Additionally, he wrote, in cooperation with others, 11 academic treatises and scientific materials totaling 35,000 words, which have played an active role in guiding the promotion and application of soybean and peanut root nodule bacteria bacterial manure.

Use of root nodule bacteria bacterial manure on soybeans and peanuts is characterized by low cost, high benefits, quick results, and great effectiveness, and it has been well received everywhere. Costs per mu are only 0.44 yuan, but net earnings obtained can be as high as more than 10 yuan. Not only does it improve protein content, but effectiveness in increasing yields is outstanding. In 1979, root nodule bacteria bacterial manure was used on only 34.5 mu of pulses and peanuts in Liaoning Province. In 1981, this suddenly increased to 900,000 mu for increases in soybean yields averaging 29.9 jin per mu (a 10.5 percent increase), and an increase in peanut yields of 37.6 jin (a 9.8 percent increase). Increases in output of soybeans and peanuts totaled 29 million jin, and net earnings of about 9.4 million yuan were obtained.

In recognition of this outstanding accomplishment in this bacterial manure research and promotion work, Ma Linxiang received a commendation from the Shenyang Municipal Microbiology Society in 1980, and in 1981 the Liaoning Provincial Academy of Agricultural Sciences designated him an advanced worker.

BRIEFS

NINGXIA RICE PRODUCTION--The Ningxia Huang He diversion irrigation area grows rice on 700,000 mu and is an old rice-growing area. Ever since the 1970's, all levels of farm technique promotion units, and research and education units in the irrigation area have cooperated closely, using various kinds of methods in vigorous promotion of newest research results. They have also summarized and upgraded traditional farming techniques of the peasant masses such as selection of fine varieties, beginning sowing in good time, culturing of sturdy seedlings, and use of chemicals to get rid of weeds. This has brought about steady increases in rice production levels and made possible consistently high rice yields over a wide area. In the 1970's, yields were only 616.7 jin per mu, but reached 975 jin per mu in 1981 for an output totaling 698.55 million jin, an all-time high for the irrigation area. In addition, five counties had rice yields of more than 1,000 jin per mu. [Text] [Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Apr 82 p 2] 9432

WHEAT FIELD MANAGEMENT STRENGTHENED

Beijing RENMIN RIBAO in Chinese 10 Apr 82 p 2

[Article: "Localities in Shaanxi Strengthen Management of Wheat Fields, Over 24 Million Mu of Wheat Generally Grow Well"]

[Text] Cadres and commune members of the localities in Shaanxi province have actively strengthened management of wheat fields, intensified spring hoeing, raking and sidedressing, and irrigation. At present, the growth trend of over 24 million mu of wheat throughout the province is generally better than past years.

During autumn planting last year, the localities in Shaanxi paid attention to economic crops and suitably increased the planting of food grains crops. This year, the total area of wheat throughout the province has been increased by 890,000 mu over the previous year.

To seize bumper harvest of wheat this year, Shaanxi Province has emphasized two tasks. One is the implementation of the agricultural production responsibility system. It has mobilized the productive enthusiasm of cadres and the masses. The second is paying attention to scientific management of wheat. Since the beginning of this year, the Provincial Chinese Communist Party Committee of Shaanxi Province and the provincial people's government have organized experts and professors of Wugong Agricultural Science Research Center twice to go deeply into the fields to inspect the growth of wheat, and they have proposed measures for management of the wheat fields. Each locality and county has also conducted widespread technical training of cadres, commune members and scientific and technical personnel, and strengthened technical guidance in field management. At present, the whole province has already irrigated 5.47 million mu of wheat fields in spring, an increase of over 1 million mu over the same period last year, and spring hoeing and raking have also progressed more rapidly than last year. Spring application of fertilizers was also grasped more tightly. The area sidedressed reached more than 10 million mu. Now, wheat in the main wheat producing region of the Guanzhong Plain has already germinated and jointed. Because sowing was timely and management was refined, the growth trend of more than 11 million mu of dryland wheat throughout the province is prosperous. The foundation in sowing the wheat fields in the irrigated area of 10 million mu was poor, but management was in time and the growth trend is improving.

USE OF AGRICULTURAL ZONING TO PLAN FARM MECHANIZATION DISCUSSED

Xian SHAANXI RIBAO in Chinese 15 Feb 82 p 1

[Article by Correspondent Wang Yougen [3769 0645 2704] and Reporter Hu Meiyu [5170 5019 1342]: "Ankang Prefecture Farm Machinery Zoning Pilot Project-Wins Good Results"]

[Text] Ankang Prefecture's Farm Machinery Bureau has devoted serious attention to farm machinery research, and has actively launched zoning work on mechanization for agriculture and for economic diversification to win good initial results. Their experiences in the Pingli County pilot project farm mechanization zoning research have received serious attention from higher authorities and units concerned.

For many years in the process of developing farm machinery in Ankang Prefecture, because zoning work did not keep pace, the purchase and promotion of farm machinery lacked scientific basis, and contained a certain element of blindness. This has led to many farm machines now being "dead in a shed," and some have been scrapped, causing waste, while agricultural and economically diversified production and processing urgently in need of farm machinery has had to rely on hand operations. As a result production has developed slowly, and the contradiction of agriculture and sideline occupations competing for labor has gone unsolved for a long period of time. Following the Third Plenary Session [of the 11th Party Central Committee], the Ankang Prefecture farm machinery system conscientiously summarized this lesson of experience, and recognized the important role of farm machinery zoning work in development of farm machinery endeavors. In November 1979, the Prefecture farm machinery bureau organized manpower to begin work on the Pingli County pilot project on farm mechanization zoning. First they went through a large amount of original materials to make a major investigation and analysis of natural conditions in the county with a close bearing on farm mechanization, and of socio-economic conditions and the agricultural production situation, after which they divided the entire county into three mechanization districts on the basis of different characteristics, and carried out exploratory studies on each of them. In the course of explorations, they conducted discussions about the emphasis, methods, and steps to be taken in agricultural mechanization in the short term and over the long term in each mechanization area, and they worked out a system of complete sets of farm implements for use in the fileds, on farms, for plant protection, for hauling, for drying, for irrigation and drainage, for the capital construction of farmland, for economically diversified production, and for the processing of agricultural sideline products. They also conducted special discussions about problems in the mechanization of tea, wood fungus, raw lacquer, and medicinal herb, which are the four staple native products. After the zoning work unit had worked for more than 5 months, it came up with a comprehensive zoning of farm mechanization in Pingli County, prepared a farm machinery comprehensive zoning map and 12 factorial maps, completed 27 different kinds of pertinent data and statistical tables, and wrote four special articles.

Results of zoning research provided a scientific basis for the county's agricultural mechanization, pointed the way to correct development, and provided new items for research in development of farm machinery. Following an interrelated program of zoning, planning, and implementation, some agricultural and economically diversified production and processing experiments have been conducted on the basis of zoning requirements, and the county farm machinery company has readjusted its farm machinery purchase and sales programs on the basis of zoning requirements.

SHAANXI

FLOOD DAMAGE REPAIR, WATER FACILITIES IMPROVEMENT REPORTED

Xian SHAANXI RIBAO in Chinese 5 Feb 82 p 1

[Article by Qin Shui [4440 3055]: "Heartening Achievements in Farmland Water Conservancy Construction in Shaanxi Province Last Winter"]

[Text] Last Winter farmland water conservancy construction in Shaanxi Province reversed a situation of continuous decline during the past several years to make new progress. Statistics from departments concerned show an increase by more than 100,000 mu in the effectively irrigated area, the leveling of 310,000 mu of land in the irrigated area, the building of 100,000 mu of fields from which a harvest can be assured despite drought or waterlogging, and the new building of 128,000 mu of "four fields," all of which was greater than during the winter of 1980.

Reasons for these achievements were, first of all, diligent strengthening of all levels of leadership. All prefectures (or municipalities) and counties summarized the lessons of experience of previous years, eliminated the effects of "leftism" from farmland water conservancy construction, and unified their ideological perceptions. In late fall and early winter, they made specific deployments. In Shanluo Prefecture, mobilization was done level by level from the prefecture down to production teams. Numerous county and commune leadership comrades went down to the grassroots to give on-site guidance, and to work together with the masses. Second, cadres and the masses in Hanzhong Prefecture and in central Shaanxi learned a lesson from the particularly severe flood, and realized that a good job of farmland water conservancy construction is one of the major elements in improving ability to cambat disasters. After summarizing the lessons of experience, they set about repairing the water damaged projects with great zeal. Hanzhong Prefecture began work to restore water-damaged projects at more than 6,800 sites, finishing the job on more than 2,300 of them. They restored 136,000 mu of water-damaged farmland. Irrigation has been restroed to 15 of the provinces 18 irrigation districts larger than 10,000 mu. Baoji municipality started work on 640 of them. It restored an irrigation area of 630,000 mu, and irrigated 310,000 mu more than during the previous year. Third was fairly complete arousal of the masses. In Qianyang County last winter, 80 percent of the production brigades, and 65 percent of the production teams began to repair fields and level the land. Thirty percent of the workforce in the county got underway on 5,900 mu, completing work on 4,900 mu. Last year a total of 580,000 mu in the irrigated areas of the province were leveled, more than half of it during the winter season. Fourth, institution of agricultural production responsibility systems played an advancing role. In all places in which various forms of responsibility systems had been put into effect early and well, farmland water conservancy construction was universally well done. After Dingbian County instituted a "double contracting" responsibility system, it vigorously developed construction of small wetland gardens served mostly by dug wells and wells with waterwheels, overfulfilling twofold its assigned expansion of the effectively irrigated area. In the five gravity-flow irrigation areas, 35 pumping stations, and more than 1,000 wells in the county, Huayin County established management responsibility systems that improved benefits from existing water conservancy facilities.

MEANS OF MOTIVATING WORK CONTRACTORS TO IMPROVE FIELDS DISCUSSED

Xian SHAANXI RIBAO in Chinese 3 Feb 82 p 1

[Article by Yu Yan [7625 7159]: "Farmland Capital Construction Achievements Great, Quality High and Pace Fast. Shimen District CCP Committee in Luonan County Studies New Situation and Uses New Methods To Solve New Problems"]

[Text] The Shimen District CCP Committee in Luonan County has studied the new situation and adopted new methods to break the low-ebb situation in which farmland capital construction has languished since the institution of various responsibility systems. In November 1981 alone, newly built basic farmland amounted to 2,141 mu, more than double the amount required by the county, and more than 3 times as much as was done in 1978 when the most field building in recent years was done. Plot by plot measurement and examination preliminary to acceptance shows quality to be very good, investment small, and the pace fast.

An overwhelming majority of fields in this district are in the mountains, and most production teams practice the system of responsibility wherein peasant households assume full responsibility for task completion. So how is the capital construction of farmlands to be done? In the course of survey, the district CCP committee learned that following assignment of responsibility for task completion to peasant households, commune member needs for the building of fields was not less but more urgent. Peasants simply feared that the responsibility system would not endure, so they did no real work on the land. On the basis of these findings, the district CCP committee made a new regulation, namely, that in the case of newly built land resources, fixed output quotas would not change, quotas to be surrendered to higher authorities would not change, and the portion of greater earnings resulting from increased output would revert entirely to the producers. Once a form of a system of responsibility became established, when readjustment was necessary for individual plots that had been contracted for, the production team would pay just compensation for capital construction to whomever had renovated the land. In addition, it roused cadres and party members to act at once to take the lead in construction. This allayed the masses' concern. Commune members said, "The land belongs to the production team, but if we grow more grain on it, it is ours, so it is better to fix it up a little." Very quickly a bustling situation in which every household in the district was engaged in a project occurred, with people vying with each other to improve the land.

In the course of the survey, the Shimen District CCP Committee also discovered that formerly during the "mass competitions," most of the land that was improved was large plots, while quite a few odd bits and pieces and marginal, infertile land was virtually forgotten for many years, quite a bit of it becoming wasteland. After the practice of assignment of responsibility of peasant households for task completion, virtually every household had some of this kind of land for which the potential was very great. Proceeding from this reality, the district CCP committee stipulated that current farmland capital construction projects should be mostly on small parcels, and the form of organization principally households. In addition, the district's communes came up with 11 projects with great potential for increasing output. After unified planning was done, commune and brigade cadres went to every household, assigning tasks household by household, assigning plots, and stipulating quality and time for completion, providing for action by every household under a unified plan. The Zhangwan No 1 Production Team had an 0.3 mu plot of slopeland, which the production team had considered renovating for several years but feared the work required would not be worthwhile. This year after commune member Song Zhenmin [1345 2182 3046] contracted to farm it, he fixed up an area 8 meters long by 4 meters high by 1 meter wide to turn the slope into a field with consistent yields.

In view of the new situation of numerous small, scattered projects following assignment of responsibility for task completion to peasant households, the district CCP committee was particularly attentive to change in its work style to do a solid job. It also instituted a system of commensurate rewards and penalties for cadres and commune members. After each commune and brigade assigned tasks household by household on the basis of production requirements and capabilities, it had each production team send cadres to measure and check, plot by plot, the land that each household had renovated according to unified standards prior to acceptance, giving rewards for those that had been improved beyond standards, and fining those whose improvements fell below standards. It instituted corresponding rewards and penalties for the cadres in each production brigade responsible to the state for the contract. Hongyangou Production Brigade was responsible for improving 33 mu, but when a survey was made in midcourse, less than 14 mu had been done. The cadres responsible for the brigade were so upset they could not get a good night's sleep, and before dawn they went to each household to do their jobs. As a result, a total of 36 mu was completed. More wonderful was that in each commune several commune member households worked together to improve the field in a new development. For the contiguous fields they had contracted to work, they did unified planning and had unified requirements; each family working separately to treat the fields as a single tract, with very good results.

ESSENTIALS OF WINTER WHEAT, RAPE CARE OUTLINED

Xian SHAANXI RIBAO in Chinese 31 Jan 82 p 1

[Article by Science Education Department and Production Department, Provincial Agricultural Commission: "Use Scientific Attitude for Good Spring Care to Win Bumper Harvests of Summer Grain and Oil-Bearing Crops. Provincial Agricultural Experts Make Suggestions About Springtime Field Care of Wheat and Rape"]

> [Text] Editor's Note: Winning a bumper harvest in summer grain and oil-bearing crops is the main task for this year's agricultural production. Simultaneous with stabilizing and perfecting systems of responsibility for agricultural production, all prefectures should strengthen leadership for springtime field care of wheat and rape, make the most of the role of scientific and technical personnel, and use pertinent management techniques. If the time for field care is not to be lost, it must be given strict attention. Ever since the beginning of winter, the province has had but scant rain and snow, so a high degree of serious attention must be given to guarding against and combating drought.

On the eve of the lunar new year, several of the province's farm experts wrote letters to the Agricultural Commission putting forward suggestions about field care of spring wheat and rape. The Provincial Agricultural Commission felt these suggestions to be valuable and worthy of consideration by all jurisdictions.

In his letter, Provincial Academy of Farming and Forestry assistant research fellow and wheat expert, Gong Rende [7895 0088 1795] said that from the looks of wheat growth in the Yangling region of Wugong County, the major contradiction at the present time is still insufficient accumulated temperatures, which means small and weak seedlings. He pointed out that springtime wheatfield care required attention to five technical measures as follows: (1) Early harrowing and hoeing in spring to promote early development of seedlings so that spring growth makes up for winter weakness. Spring harrowing and hoeing helps raise ground temperatures, preserves soil moisture and prevents drying out, and promotes root tillering for very noticeable results in these regards. These actions were taken too late in previous years, usually after the lunar new year or even after the 15th day of the first lunar month, between 10 and 20 days later that actually required. This year there should be early mobilization, early arrangements and early action. (2) Top dressings of fertilizer in early spring. On most large areas, fertilization is still insufficent, and early topdressings of fertilizers to stimulate tillering and increase in the number of spikes, increasing by between 30,000 and 50,000 the number of spikes per mu is entirely possible. While the soil is moist, fertilizer should be applied early and deeply. In some high yield areas, the quantity of basic fertilizer and winter topdressings has already been very great, so the soil is by no means lacking in fertility, in which case there is no need for topdressings in early spring. (3) Early spring irrigation should be done. Generally speaking, early spring irrigation should be promoted in central regions of Shaanxi. This is because the irrigated area's fertility foundation has been remarkably increased, and fertilization with large quantities of chemical fertilizer can guard against defertilization. However, early spring irrigation still has to be prudently handled, and particular care must be taken in some very infertile places. However, if there was no irrigation and scant rain or snow during winter, and loose soil is very thick on the surface of the ground at the time of lunar new year, aridity being rather obvious, irrigation should be done. Irrigation should be done in concert with topdressings of fertilizer, and after irrigation has been completed the hardened surface of the soil should be broken up. If there is moisture in the soil at the time of thawing, spring irrigation should be delayed for as long as possible. In the west central region of Shaanxi Province, it may be delayed until early or mid-March. (4) In dryland wheatfields where rainfall was scant during the winter season and the soil is lifeless at the time of lunar new year, the loose layer of soil being very deep, compacting is needed to promote root development and greening up. If winter snows have been plentiful, and soil moisture is great at the time of thawing, harrowing should be done in early spring to maintain basic soil moisture and promote early greening up of the wheat. (5) This year wheat seedlings have been universally scanty, mostly because of little tillering, so action has to be taken to promote tillering and increase the number of spikes.

Provincial Farming and Forestry School teacher and wheat expert Zhang Qipeng [1728 0796 7720] said in his letter that wheatfield care should "promote early growth of weak seedlings, skillfully care for strong seedlings, and control vigorous seedlings so they do not produce runaway growth." He said that because of the large amount of overcast and rainy weather when the wheat was planted last fall, seeds were sown in muddy, watery wheatfields in some irrigation areas. This, plus the overly low temperatures of October and November, caused three problems for wheat growth. First was a tendency toward smallness of colonies. Second was a tendency toward weakness of individual plants. Third was insufficient balance. In irrigation areas, these conditions exist in about one-third of the fields. How can they be controlled? He noted that the job to be done in spring care of wheat is to assure numerous, large spikes and sturdy stems that do not lodge, the emphasis going to promotion of spikes and formation of spikes. He proposed four specific ways of doing this. First is a good job of loosening the soil and preserving soil moisture. Second is deep application of fertilizer. In view of wheat seedling growth characteristics, the thing to do is "fertilize early rather than late; fertilize deep rather than shallow; and fertilize when the soil is wet rather than when the soil is dry." As soon as the soil has thawed, while the soil is still moist, opportunity should be taken to fertilize in rows or in clusters. Third is prompt watering. In the case of fields lacking in soil moisture where seedlings are weak, when temperatures return to 3 to 5 degrees Centigrade, a light watering for greening up should be done, and after watering the soil should be loosened. Fourth is strengthening of leadership. When each county convenes its meeting of cadres from three levels, wheatfield care assignments should be made.

With respect to springtime care of rape, Provincial Farming and Forestry Institute assistant research fellow and rape expert Zhuang Shunqi [8369 7311 3825] said that the emphasis should be on maintenance of increased blanching of stems and increasing grain weight. As a practical matter, care techniques required were of three kinds. (1) Cultivation of the soil as soon as it is no longer frozen to maintain soil moisture, to loosen the soil, and to increase its temperature. Spring irrigation may be delayed until shoots begin to form for early development and growth. During the period of formation of shoots, cultivation and hilling around plants to support the roots should be done in combination. (2) During the period of greening up, early cultivation and greening-up fertilization should be done, a single fertilization sufficing. Depending on soil fertility about 30 jin per mu of standard nitrogenous fertilizer should be applied, together with 200 jin of grass and wood ashes (cooking pit ashes). The fertilizer and ashes should be applied in a ditch or put into the ground with a drill. (3) During springtime, prevention of insect pests should be done at least twice.

STATUS QUO FOR EXISTING CROP PATTERNS SUPPORTED

Jinan DAZHONG RIBAO in Chinese 9 Mar 82 p 2

[Article by Commentator: "Equitable Arrangements for Growing of Crops Under Guidance of State Plans"]

[Text] Equitable arrangement of agricultural crop patterns under the guidance of state plans for coordinated development of production of all kinds within agriculture is a major aspect of national economic readjustment. Since the Third Plenary Session of the 11th Party Central Committee, throughout the province general methods have been adapted to local situations to make the most of advantages in readjustment of the internal structure of agriculture. The area of the province sown to economic crops in 1981 increased from somewhat more than 21 million mu in 1978 to somewhat more than 27 million mu, the proportion of total area sown expanding from 13.3 percent to 17.8 percent. For the major economic crops, cotton and peanuts, all-time highs were exceeded in both area planted and output. Readjustment of crop patterns has promoted all-around development of agriculture. Gross agricultural output value for the province as a whole has increased from 11.3 billion yuan in 1978 to more than 14 billion yuan in 1981, an increase of 23.9 percent. Development of economic crops has played an important role in assisting national construction, in expanding foreign trade and exports, in guaranteeing things needed by the military and used by civilians, and in increasing collective and commune member income. Analysis on the basis of natural conditions, population density, the present state of the proportion of cultivated land, and historical development, shows that the present agricultural crop patterns in Shandong Province are substantially equitable following several years of readjustment. Henceforth, except for a little readjustment still required by a minority of units, the overall planting area should be maintained substantially the way it now is, and the emphasis should go to improvement of yeilds per unit of area and to improving specie quality in an effort to improve economic benefits.

The agricultural economy is a major integral part of the entire national economy, and it is necessary to adhere to a program in which the planned economy is foremost, market regulation ancillary. During the previous stage, after emphasizing respect for the self-determination of production teams and instituting various forms of production responsibility systems, a situation developed at various places of "grow whatever is profitable" in planting and of "sell to whomever pays the msot money" in the sale of agricultural products, with no consideration of the country's need, no obedience to state plan guidance, and no honoring of contracts. This is a problem deserving of extremely close attention. It should be recognized that under the past "leftist" ideological guidance, we did not seek to adapt general methods to local situations, but practiced the growing of a single kind of crops, and elbowed economic crops aside, impairing the bringing into play of advantages everywhere and the earnings of the masses. This was a painful lesson. Marxism tells us that all things are mutually related and mutually restrictive, and that after a certain limit is exceeded, a change in the opposite direction begins. When truth goes a step too far, it becomes falsehood. This is likewise true for the readjustment of agricultural crop patterns. When it goes against natural laws to exceed objective needs and capabilities, it also gives rise to an opposite reaction. Unless we limit expansion of the economic crop area, a great reduction in the grainfield area will be created, and it will become impossible to assure the fundamental needs of the country and the people for grain, while at the same time development of certain economic crops may exceed the extent of growth of processing and transportation capacity creating overstocking and waste, a new proportional imbalance taking place that may even urgently require further readjustment. Such would be extremely disadvantageous for development of the agricultural economy and the economy of the entire country. Consequently, we must equitably arrange the growing of crops in accordance with requirements layed down in the state plan, diligently handling this matter as a strategic issue in development of the agricultural economy.

Shandong is a large province with a population of more than 70 million in which the problem of getting enough food to eat is a large one. Its grain production has yet to be solved, and the contradiction between production and demand is still rather prominent. Use of grain to meet the annual natural rate of population increase, for the livestock industry, for industry, and for other purposes requires year by year increases. Today, in a situation in which our material and technical situation is limited, when the damage done by natural disasters is fairly great, and when grain yields per unit of area cannot be greatly increased for the time being, it is all the more necessary to maintain a prudent attitude about decreasing the grain growing area. Of course, when we expand the economic crop area, the state allocates grain to us, but there are definite limits to this, after all. We must base ourselves on a foundation of self-sufficiency in grain within the province. This is the premise that we must first consider in readjustment of the agricultural crop patterns.

In the development of agriculture, it is necessary conscientiously to institute a policy of "positively no slackening of grain production while actively developing economic diversification." In planning the crops to be grown, all jurisdictions must submit to the situation as a whole; both making of the most of their own advantages, and proceeding from the situation as a whole; both considering how to make the most advantage of economic crops, and considering how to make the most advantage of economic crops. This year the grainfield area must first be stabilized at its present level with no further reductions, and efforts are to be made to increase yields per unit of area for both grain crops and economic crops for a steady improvement in levels of average per capita grain production. In the development of economic diversification, most important is use of barren slopes and wasteland beaches, the water surface of ponds, the shores of lakes and oceans, and the four besides [beside roads, streams, houses, and villages, and the 10 sides [small plots of land of many kinds] with no encroachment on grainfields. Wherever the land is suited to the growing of grain, the overall situation must be taken into consideration and the general interest recognized, active development of grain production being done in accordance with state plans in order to have the honor of providing the country commodity grain. Likewise in areas that grow predominantly cotton, it is necessary first to assure grain self-sufficiency for the agricultural population and to achieve complete self-sufficiency with all possible speed. Provided requisition grain procurement quotas have been fulfilled and task completion obligations have been fully met, other areas may develop economic crops as appropriate. In a situation in which the farflung rural villages have instituted various forms of production responsibility systems, and particularly in places and units that practice production responsibility systems of fixing output quotas on a household basis or fixing full responsibility for task completion on a household basis, more attention is required to solve this problem well. The way is to enhance state planning guidance for the growing of crops, using economic contracts to dovetail the production activities of the collective and of individual commune members with state plans, implementing state plans in each and every production unit, and peasant household, and on individual commune members, leading to peasant development of production on the basis of national needs, prevention and correction of blindness and lopsidedness in production, and preservation of mass enthusiasm for socialism.

In promoting various forms of production responsibility systems, we are developing systems of responsibility for the socialist rural economy. In respecting the self-determination of production teams, we are respecting self-determination to obey state plan guidance, the goal being arousal of collective and individual commune member enthusiasm. After long tempering in revolution and construction, the broad masses of commune members in the province wholeheartedly support socialism. It is subjectivist blind guidance and irrational burdens that they oppose, it positively is not the party's leadership and state plan guidance. All levels of CCP committees, the government, and grassroots cadres in the farflung rural villages must enthusiastically organize the commune member masses and, under guidance of the state plan, combine the needs of part of society and of society as a whole, correctly handle the interests of the country, the collective, and individuals, and equitably plan the crop growing area for greater development of grain, of economic crops and of economic diversification to win an all-around bumper harvest in agriculture this year.

LOCAL PROCESSING OF FARM PRODUCTS ENCOURAGED

Jinan DAZHONG RIBAO in Chinese 7 Mar 82 p 1

[Article: "Devote Earnest Attention to Local Processing of Agricultural By-products"]

[Text] Basing oneself on local resources for energetic development of agricultural product processing industries, and taking the path of adding value several times from production to processing to marketing is a major way in which to increase the agricultural commodity rate, and to increase both collective and commune member income. All jurisdictions should treat this issue as an important matter and take it diligently in hand to produce results.

Ours is a vast province with superior natural conditions in which the potential is very great for use and development of resources. During the past several years in particular, rural economic diversification has developed rapidly, and economic crops such as cotton and oil-bearing crops have tremendously increased output to open broad prospects for development of agricultural products processing industries. Staples include grain, cotton, and oil, dry products [such as nuts, wood fungus, and lily buds] and fresh fruits, as well as aquatic products, all sorts of vegetables, and grasses and willow used for plaiting, etc. If these resources could be fully used for local processing, both the commodity utilization rate and their economic value could be increased and state, collective, and individual earnings increased, and difficulties in marketing, storing, and hauling products could be diminished for a genuinely fine situation of killing many birds with a single stone. However, some rural communes and brigades have yet to emancipate themselves from the past old rigamarole of single crop production and sale of agricultural raw materials, and the scope of their processing of agricultural products is very small. As a result many products that might be processed locally are hauled away from rural villages to cities as raw materials and then hauled back and sold in rural villages after processing. A trip out and a trip back both increases pressures on transportation, and increases costs, which is very much not worthwhile. Consequently, we must follow rational economic principles and vigorously develop commune and brigade agricultural product processing industries in a fundamental reversal of this irrational situation. It should be realized that for commune and brigade development of agricultural by-product processing industries the raw materials are ready made and the workforce abundant. Furthermore much is processing of products to eat, to wear, or to use, and generally speaking, investment required is small, results show quickly, and markets for products are good. Such industries can steadily develop over a long period of time and are superior in many ways to development of industries that rely solely on "looking for rice to put into the pot." Once the focus of production has been shifted in this direction, commune and brigade enterprise's production will have more vitality.

Operation of agricultural by-products processing industries requires adherence to the principle of solid, steady development. All jurisidctions will have to adapt general methods to local situations to carry out a resources survey and arrange priorities for products, proceed from existing realities, formulate development plans and implement measures, have a central focus and work step by step, with positively no rushing headlong into mass action or blindly blundering ahead. Planting and breeding industries, and economic diversification are the foundation for agricultural product processing; thus, formulation of plans must be closely combined with these two things, and particular attention should be given the building of planting and breeding bases using planting and breeding to protect processing and using processing to promote planting and breeding so that planting, breeding, and processing form a coherent whole for coordinated development. The foundation for rural agricultural products processing industries is presently weak and requires support from all sides. Industrial units can organize techniques and equipment to go to the countryside to work jointly with communes and brigades. All jurisidctions should act in accordance with state plans for supply to communes and brigades of various agricultural products for processing, setting suitable base procurement figures and proportion for amounts procured and amounts regained to achieve both assurance of fulfillment of state requisition procurement and quota procurement tasks, and take care of commune and brigade requirements for the development of processing industries. Attention should be given the training of technical forces for steady improvement in quality of agricultural product processing. In addition, as production develops, efforts should be made to open circulation channels and do a good jop of supply and marketing to impel commune and brigade enterprises to steadily walk the path of a combination of planting, breeding, and processing, carrying on production, supply, and marketing as a coherent whole to win greater economic benefits.

EFFORTS CONTINUED TO FIND, STORE WATER DURING PROTRACTED DROUGHT

Jinan DAZHONG RIBAO in Chinese 9 Mar 82 p 2

[Article by Chun Pu [2504 0944], Tsng Nian [0681 1628], Lin Qi [2651 3305] and Xi Xiang [3556 4382]: "Store More Water; Use Water Well, and Expand Irrigated Area. Weifang Prefecture Stirs the Masses to Combat Drought and Protect a Bumper Harvest"]

[Text] Weifang Prefecture's 250,000 people have pitched in to use every means possible to tap water resources to combat drought and protect the wheat to win a bumper harvest. At the present time work has been completed on 4,618 of the prefecture's 6,823 water conservation projects on which work had been started. Newly sunk wells number 1,472, increasing and improving an irrigated area of 700,000 mu.

For the past several years Weifang Prefecture has had continuous drought. Since January this year, rainfall has been 46 percent less than during the same period in most years. Analysis of measurements of soil moisture show a drought area covering 8 million mu including 3 million mu of wheatfields. In order to triumph over the drought, since last year, prefecture and county leadership organizations have organized more than 10,000 people into work teams to go everywhere to arouse the masses to use every available means to tap water sources. Many counties and communes have organized forces to dam places along rivers or cut off the flow of phreatic water, directing the water to replenish sources. They have built a group of rudimentary water pumping stations, using multiple level water raising methods to make maximum use of both the visible and the phreatic water in river beds. Places that cannot be watered for the time being are cycling use of water. They first raise the water to fill ponds at the bends of streams or water pits by way of preparing sufficient water sources for further watering of the wheat or for doing spring sowing. Statistics from Yidu, Zhucheng, Anqiu, and Linju counties show that this method is being used to store more than 10 million cubic meters of water. On plains areas where wells can be sunk, special teams were organized to sink pump wells. In coastal, mountain and hill, and underground red callys areas, large mouthed wells continue to be sunk, and rectangular pools, gallery wells, and small pressure wells are being dug. Recently Pingdu County organized more than 30,000 workers to begin work on more than 600 small water conservancy projects of various kinds requiring little investment of funds for quick results. Now 450 of them have been completed, more than 50 pump wells dug, and an irrigated area of more than 60,000 mu newly added or improved. Gaomi County has used regulations at every level to formulate and implement a bonus policy for digging for water. In less than 1 month following the lunar new year, 1,000 newly dug pump wells or large mouth wells were opened in the county, pumping stations were built at 11 sites, and rivers were dammed or diverted at 68 places. In addition, while digging for water and storing water, all jurisdictions have taken active measures for the conservation and scientific use of water.

COTTON PLANTING AREA STABILITY, SINGLE CROP INCREASE EMPHASIZED

Beijing RENMIN RIBAO in Chinese 8 Apr 82 p 2

[Article: "Correctly Handle the Relationship Between Food Grains and Cotton, Implement This Year's Cotton Planting Plan; Shangdong Emphasizes Stabilizing the Area To Increase Unit Yield"]

[Text] Report by NEW CHINA NEWS reporter Jia Jianzhou [6328 1696 5297]: While implementing this year's cotton planting plan, the Provincial Committee of the Chinese Communist Party in Shandong and the provincial people's government repeatedly emphasized that each locality must correctly handle the relationship between food grains and cotton, stabilize the area, place major efforts on unit yield, increase total yield, and seize double bumper harvests of food grains and cotton.

After the Third Plenary Session, each major cotton producing area in Shandong Province started out by developing the natural superiority of the locality, actively and steadily readjusted the proportion of food grains and cotton, expanded the area of cotton fields, and enabled the total yield of cotton to surpass 10 million dan consecutively for 2 years. This served importantly to guarantee that the nation's cotton production will increase in yield. The cotton farmers have also realized more and more economic benefits. This year, the enthusiasm in planting cotton by each cotton producing region in Shandong Province is very strong. The provincial committee and the provincial government believe that under the present situation under which the proportion of the areas of food grains and cotton are basically rational, future attention should be paid to stabilizing the area of cotton fields and to exert major efforts in unit yield, in increasing total yield and in seizing overall bumper harvests. In particular, major efforts should be in increasing the unit area yield.

Data provided by concerned departments indicate that the potential to increase the unit yield of cotton in Shandong Province is great. Last year, the average per mu yield of 30 counties was lower than the province-wide average. They had over 6 million mu of cotton fields. If the per mu yield of these cotton fields could be raised to last year's average for the whole province, total yield could be increased by more than 1.2 million dan. In addition, low yielding cotton fields could produce a large-scale increase, and even high yielding cotton fields could continue to increase their yields. The counties of Gaotang, Pingyuan, Ningjin, Jinxiang increased their per mu yield by more than 10 jin on the basis of producing a per mu yield of 100 min last year. The provincial committee and the provincial government believe that now, the whole province has already acquired the favorable conditions to increase the unit yield of cotton. For example, the party's policies have been profoundly accepted by the people. The production responsibility system has been further perfected, and the productive enthusiasm of the cotton farmers is high. Capital construction of farmland has had new development. The ability to resist disasters has been further strengthened. Fertilizers, farm chemicals, machinery and capital have all been increased from past years. The material foundation is more abundant, etc. Therefore, placing emphasis on increasing unit yield of cotton production is consistent with the actual situation in the production of cotton in Shandong Province. At the same time, the provincial committee has requested each locality to greatly increase the unit yield of food grains so that there will be more counties, communes and brigades producing double increased yields of cotton and food grains.

Recently, the Provincial Committee of the Chinese Communist Party of Shandong and the provincial people's government held a province-wide cotton production conference in Ling County. The conference discussed problems concerning ways to increase the unit yield of cotton and proposed corresponding measures to increase yield.

EXHORTATION ISSUED ON SIGNING OF RURAL FARM CONTRACTS

Chengdu SICHUAN RIBAO in Chinese 5 Apr 82 p 1

[Article by Commentator: "Take Firmly in Hand the Signing of Rural Economic Contracts"]

[Text] Right now all jurisdictions are in process of implementing the Central Committee documents on rural work and signing rural economic contracts. This is extremely important for assuring this year's growth of agricultural production and implementation of various plans, in carrying out policies of "concurrent concern for the three" [the country, the collective, and individuals], and in perfecting production responsibility systems.

Generally speaking the signing of economic contracts in the province's rural villages has been done better this year than last. One obvious characteristic has been that large numbers of leadership comrades in the province, prefectures, and counties have personally taken charge. Not only did they start early, act quickly, and take matters firmly in hand, but work was also solidly done. Attention should be directed to those places where progress has been slow and cases in which many contracts, particularly this year's production contract agreements, have yet to be signed. Though some have been signed, they are fairly careless or even simply a mere formality. The main reason for this is that some leadership comrades lack sufficient understanding of the importance of signing contracts, do not devote sufficient attention to them, and do not come to grips with the matter. In some places it is because some genuine problems have not been promptly handled well. Some commune members onesidedly emphasize their own benefit without being very much concerned about benefits to the country and to the collective.

Contracts are an effective assurance that state economic plans will be carried out. They are like a bond that links together the various individual links of production, exchange, and distribution to the welfare of the country, the collective, and individuals. Inasmuch as most rural villages in Sichuan Province have instituted "double contract" systems of responsibility [fixing output quotas based on households with peasant households assuming full responsibility for task completion], it is necessary to assure that state plans be carried out, that leadership of agricultural production be planned, and that there be proportional development. The most effective way of doing this is to promote contracts. Consequently, the signing of rural conomic contracts positively is not a small matter that can be done or not; rather it is an imperative matter to which efforts must be devoted and which must be taken firmly in hand. All levels of leadership comrades must have a clear understanding of this point.

The contracts that must be signed in rural villages have many aspects. The thing that is most important right now is to make sure that production contract agreements are signed as soon as possible between production teams and commune members so that contracts can be used, in advance of spring plowing, to implement this year's agricultural production plans in order to assure that production will be done in accordance with plans. After this has been done, state procurement units concerned should promptly organize to sign agricultural and commercial agreements with production teams to give reality to agricultural product procurement plans handed down by the state. No matter whether production procurement contract agreements or agricultural-commercial agreements, both should be signed in accordance with economic contract laws and pertinent provincial regulations so that their contents will be complete and procedures detailed as an aid both to conducting checks and honoring them.

A good job of signing contracts requires that work be done well and genuine problems conscientiously resolved. Further propaganda and mobilization work has to be done to increase the understanding of the broad masses of cadres and people. Ideological and political work among the peasants has to be enhanced to educate and lead them to correctly handle the three relationships to consciously sign and carry out agreements, and to strive to do their best to discharge obligations. The contracts' economic norms will be set largely in accordance with state plans, but the masses should be aroused to carry out full discussion and consultation so that the contracts will be realistic, positive and reliable, and allow for unforseen circumstances. Withholdings by the collective should be made on the basis of what local economic development permits. Tax payments are to be assured of fulfillment, and cadre allowances, care of the dependents of martyrs and military personnel as well as of households enjoying the five guarantees [childless and infirm old persons who are guaranteed food, clothing, medical care, housing and burial expenses] should be guaranteed. Contracts are to be signed on a foundation of strict attention to the perfection of responsibility systems, and the signing of contracts should be used to improve and stabilize responsibility systems.

The all-around promotion of economic contract systems in rural villages is a major reform in administration and management that touches on many matters. It has strong policy overtones and requires a lot of work. But since experience is lacking, right now strengthening of concrete leadership is urgently needed. In communes and brigades in which progress has been relatively slow, in particular, leadership comrades must go forward to help promptly study and solve existing problems, signing contracts as rapidly as possible. In places that have already signed contracts, continued checking and examinations must be done; omissions must be filled and revisions made so that the contracts do not become perfunctory.

Right now the busy season of spring farming is at hand, yet the work of signing contracts has not been completed. All jurisdictions must closely coordinate with spring farming and production by intensifying work and strive to continue signing rural economic contracts in advance of the extremely busy spring farming season to assure fulfillment of this year's agricultural production plans.

INDUCEMENTS PROVIDED TO ENCOURAGE SOW PRODUCTION

Chengdu SICHAUN RIBAO in Chinese 8 Apr 82 p 2

[Article by Jin Yansuo [6855 1693 2747]: "Give Earnest Attention to the Raising of Sows"]

[Text] For steady and continuous development of hog raising, a certain number of sows is required to guarantee ample breeding stock. Statistics from units concerned show that as compared with the same period during the previous year, in 1981 a six percent decline occurred in the number of sows in the province. Today the ratio of sows to hogs in inventory has declined from 1981's 6.75 percent to 6.5 percent. Particularly deserving of attention is that in key commodity hog producing areas, the decline in the number of sows has been even more conspicuous. Unless vigorous action is taken at once to change this situation, inevitably Sichuan Province's hog raising will be seriously impaired. It will not hurt to do some figuring of accounts here.

The first account. At the beginning of this year, hogs in inventory in Sichuan Province numbered 50.23 million. According to forecasts from units concerned, on the basis of the number of hogs removed from inventory in 1981, the number of hogs that will be removed from inventory in 1982 will number about 33 million. In order to have the current 50 million head in inventory at the end of this year, a corresponding number of shoats will have to be added to the stys.

The second account. Sichuan Province now has 3.26 million sows. On the basis of the 1981 shoat survival rate, it is estimated that during the present year, about 29.34 million shoats will be added to the hog population. Unless more sows are raised, by the end of the year the number of hogs in inventory in Sichuan Province will number only about 46.57 million, which will mean a 7.3 percent decline from the same period last year.

The third account. In order to maintain the hog population at the beginning of next year at its present size, the province as a whole will have to raise an additional 400,000 to 500,000 sows. To meet this requirement, the proportion of sows to hogs in inventory in the province as a whole will have to increase from the present 6.5 percent to about 7.5 percent, and be no lower than 7 percent.

From the above three accounts it can be clearly seen that action has to begin right now to give earnest attention to the growing of sows.

For many years two different enthusiasms have been brought into play in the raising of sows in Sichuan Province, namely both advocacy of collective raising and encouragement to individual commune members to raise them. However, in both collective raising and raising by private individuals there have been problems in economic benefits. After shoats born of sows that peasants have raised have been sold, the peasants want to be able to make up for the materials consumed and the living labor expended in raising the sows, and they want to have certain net earnings as well. If they do not, the peasants' enthusiasm for raising sows will be damaged. In order to encourage peasants to actively raise sows and to raise them well, the state has acted to make award sales of four jin of grain for every shoat. For every sow privately raised by a commune member, collectives have alloted between 1 and 2 fen of land for the growing of fodder. At the time of distribution of feed grains, a general 50 to 60 jin of feed grain is distributed for each sow, and 4 to 5 jin for each shoat. In figuring manure provided by hog growers and distribution of green feed, the standard for calculation is generally one sow equals two fat hogs. Thus, when market prices are normal, a commune member's economic benefits from the raising of sows are generally equal to the economic benefits from raising fattened hogs. Ever since 1980, as a result of "difficulty in selling hogs," shoats have been a drug on the market, and large numbers of sows in rural areas have been sterilized. Within the space of 2 years, sows decreased by about 1 million. Even though market prices for shoats went back up last year, the number of sows raised continued to decline. In order to have consistent raising of sows, methods that production teams use to regulate hog production cannot be weakened. The former series of methods used to encourage commune members to raise hogs (including sows) must be made an important part of the improvement and perfection of agricultural production responsibility systems, and should be revived and implemented as rapidly as possible.

In the revival and implementation of the series of methods used in the past to encourage commune members to do a good job of raising sows, general methods will have to be adapted to specific situations. In places practicing assignment of output quotas to teams, contracting jobs to be done in a certain period of time, and "four specializations with a single contract," both collective and individual raising has to continue to be advocated for the development of sow production, and appropriate increases should be made in the amount of feeding done where conditions permit. Either specialized households may feed and raise the hogs, or hogs may be collectively owned but privately raised. In cases in which individual commune members privately raise sows, production teams should adhere to formerly instituted methods of providing bonuses. Nanquan Commune in Chongqing Municipality used contracts with specialized households at its collectively owned hog raising farm, combining "breeding and raising." It held to feed grain withholdings for private sow raising, making award sales of 10 jin of grain withholdings for every live shoat, and this year the number of sows has begun to increase steadily.

Production teams practicing assignment of output quotas to individual able-bodied laborers, and fixing output quotas on a household basis should adhere to a system whereby withholding of feed grain and distribution of feed grain is done centrally by production teams. Feed grains divided up for the feeding of sows should not be allowed to fall below levels prior to the practice of fixing output quotas on a household basis. After Wan'an Commune in Shuangliu County instituted "double contracting" [fixing output quotas on a household basis and assigning full responsibility for task completion], it arranged for feed grain on the basis of the number of head raised in 1982, 60 jin of feed grain per hog being provided from feed grain withheld by production teams, and between 200 and 280 jin per sow (feed grain for shoats included) being provided. If no hogs were raised, the grain was returned to the production team. During this year the number of sows has increased throughout the commune.

In places practicing large scale assignment of responsibilities, hogs and land may be linked, a certain amount of land for the growing of fodder being assigned to commune members, depending on the number of sows they raise. In short, it is necessary to act on the basis of the new situation following institution of various forms of production responsibility systems to give tailored guidance, and to make arrangements production team by production team to reverse the present situation of continued decline in the sow population.

PROVINCIAL STATE FARM ACHIEVEMENTS REVIEWED

Chengdu SICHUAN RIBAO in Chinese 5 Apr 82 p 1

[Article by State Farm and Land Reclamation Bureau: "Experiences Summarized and Achievements Carried Forward For Further Fine Operation of State Farms. Sichuan Province's State Farm Employees Triumphed Over Exceptionally Great Flood Disasters Last Year to Win Heartening Achievements in All Kinds of Production. They Are Determined to Increase Output This Year of More Commodities to Make a Greater Contribution to the Country"]

[Text] By summarizing experiences, commending the advanced, arousing the will to fight, determinedly carrying forward achievements, and making advances in the operation of enterprises, Sichuan Province's state farm and land reclamation system farm employees have increased output of commodities and have made greater contributions to the country.

Last year, Sichuan Province was stricken with exceptionally great flood disasters, which brought serious disaster to 46 farms causing almost 4 million yuan damage. In order to make up for losses caused by the floods, all farms diligently put into force a program of "taking one industry as the primary one, with economic diversification." While operating the primary industry well, on the basis of raw materials, manpower, land, and technical conditions each farm adapted general methods to local situations to launch economic diversification and industrial sideline production, and operated processing plants for tea, fruits, and dairy products. Industrial sideline occupation output value for the year as a whole amounted to 70 percent of gross output value from agriculture. In addition, in light of the new circumstances that have arisen in the operation of integrated agricultural, industrial, and commercial enterprises, and in enterprises jointly run by state farms and production teams, they conscientiously propagandized the party's programs and policies, promptly studied the new circumstances, and solved new problems. Not only did this bring about a consolidation of integrated enterprises, but also brought about an upgrading of quality as well. In order to arouse to the full the enthusiasm of staff and workers, each farm adapted general methods to local situations to establish various forms of responsibility systems. Some farms proceeded on the basis of "three fixeds and one reward" to try out the linking of output to teams or to individuals, output in excess of quotas being divided among them. Some farms tried out the calculation of bonuses (or compensation) on the basis of output, bonuses being given for output in excess of quotas and penalties levied for shortfalls. This directly linked earnings to staff and workers and to output and profits, and linked rights, responsibilities, and benefits to produce fine economic benefits. In addition, simultaneous with improvements in the workstyle of leaders and the carrying out of ideological and political work, each farm intensified scientific research work and the technical training of staff and workers to improve staff and workers' technical and management levels, thereby winning remarkable achievements in turning losses into profits through scientific farming and livestock raising. A comparison of 1981 with the year before shows that except for fruit output, which fell in an off year, output of major products including cow's milk, the rhizomes of Chinese goldthread (Coptis chinensis), and tea increased by between 2 and 11.8 percent. The number of yaks and sheep increased by 15.3 percent; gross output value of agriculture increased 34.2 percent; tax revenues increased 67.96 percent; and profits increased by 37.5 percent for all-time highs. Furthermore 31 advanced collectives appeared that had provided the country with large amounts of commodities, high profits, and had made great contributions. Included among them was the Huanglian Integrated Enterprise Company in Shizhu County, Jinyunshan Horticultural Farm in Chongqing Municipality, Liuli Dairy Farm in Chengdu Municipality, and Houshan Tea Farm in Shuyong County. Advanced individuals totaled 49, including He Huanzhou [0149 3562 0719], Liu Runxian [0491 3387 0341], Wang Meifu [3769 5019 4395] and Zhan Guifa [6124 6311 4099].

After having summarized experiences, staff and workers at farms in the provincial state farm and land reclamation system determined to conscientiously programs and policies for agricultural and land reclamation work, and to mobilize staff and workers to develop production through every available means to assure fulfillment and overfulfillment of this year's quotas for principal and sideline occupation production, and to provide the country with greater amounts of commodities. From leadership energies to workforce assignments, from use of funds to supply of materials, priority went to satisfying needs of agricultural production. In addition, economic diversification and processing industries were vigorously developed. Farms and all levels of management units should help integrated enterprises and enterprises run jointly by state farms and production teams to conscientiously summarize experiences for further consolidation and development. All enterprises are to strictly carry out the party's programs and policies to assure fulfillment of state requisition procurement tasks. All farms should further improve assignment of sole responsibility for financial matters, three fixed and one reward, and such various forms of production responsibility systems, properly handling the welfare of the country, of the farms, and of staff and workers, arouse staff and workers to actively improve their technical and management levels, and strive to run state farms well to make a new contribution to national socialist construction.

MARKETS FOR FARM PRODUCTS; FARM PRODUCTS FOR MARKETS DISCUSSED

Chengdu SICHUAN RIBAO in Chinese 1 Feb 82 pp 1, 4

[Article: "One Hand on Production and the Other Hand on Circulation. Experiences of the Dazhu County CCP Committee in the Strengthening of Leadership of Finance and Trade Work"]

[Excerpts] In meeting new circumstances in rural economic development, the Dazhu County CCP Committee has diligently and intensively studied new problems in the circulation field, persevering in keeping one hand on production and the other hand on circulation. In 1981, the county's gross output of grain increased by 10.6 percent; gross earnings from agricultural sideline occupations increased 18.4 percent; and gross output value of industry increased 15 percent. Financial and trade work overfulfilled the plan for the year 56 days ahead of schedule. Up until 1978, county revenues were in the red, but as of 1981 the county had reserves of 1.6 million yuan.

Dazhu County's reliance on policies and science during the past several years has brought about rapid increase in the growth of agricultural production and a rise in the peasants standard of living. In order to further increase peasant earnings, the county CCP committee began with readjustment of agricultural production, directing production teams and peasants to develop economic diversification to increase commodity output. However, following development of economic diversification, frequently impediments in circulation channels made it difficult to sell certain goods, which impaired peasant desire to produce. Formerly some comrades did not attach sufficient importance to such problems, always supposing that if production could be kept up and goods were produced, circulation would naturally be all right. The new situation in development of a rural commodity economy has made county CCP committees realize the lopsidedness of such a point of view. Since 1979, the county CCP committee has repeatedly stressed both the need to realize that production determines circulation and that circulation reacts on production, and that under certain conditions, circulation may play a decisive role on some production. For example, as a result of the reduction in 1978 of procurement of burley tobacco and chilli peppers, which had enjoyed brisk sales, output plummeted the following year. As a result of the steady opening of markets for piemarker, procurement gave impetus to marketing, and marketing gave impetus to production, so output climbed year after year. The county CCP committee used these actual examples for repeated indoctrination of cadres at all echelons to show that in agriculture it is not enough just to work at agriculture, one has to enliven commerce as well.

The experience of Dazhu County's CCP Committee in giving attention to commodity circulation was, first of all, perseverance in the planned nature of the socialist economy and unremmitting indoctrination of the peasants in a deep love for socialism and obedience to state plans. Until such time as procurement of goods for the state plan has been fulfilled, there can be no dealing in any other channels. At the same time, provided the main channels can assure fulfillment of state procurement plans, flexible and accommodating methods may be used to develop multiple channel dealings to make full use of the supplemental role of market regulation to enliven circulation. Because it has carried out correct policies, for 4 consecutive years the county has overfulfilled state procurement plans for agricultural sideline goods. In August 1981, before the major producer of day lilies, Qingshui Prefecture, had fulfilled state procurement plans for day lilies, Miabo Commune and Brigade enterprises raised prices and bought preemptively. The county CCP committee charged the industrial and commercial executive management department with making a solemn investigation to recover the day lilies that had been bought to assure fulfillment of state procurement plans. In 1980, the county had a bumper harvest of citrus fruit, and after production teams had fulfilled requisition procurement quotas to the letter, a very big surplus remained. In recognition that citrus fruit is a perishable commodity that will rot if not promptly sold, thereby causing losses, the county CCP committee proposed dealing through multiple channels, sales being promoted both locally, and the fruit being hauled elsewhere for sale. This prevented the citrus from rotting and increased peasant earnings. In 1981 and the 2 previous years, great development occurred in rural hog production and hog procurement outpaced demand for a time. Proceeding with a desire to protect peasant enthusiasm for hog raising, the county CCP committee resolutely decided that the county food company should shoulder more of the peasants' hardships, and also began dealings through multiple channels, the 200,000 peasant households thereby each averaging sale of half a commodity hog. In 1981 the county removed 450,000 hogs from inventory and had an inventory on hand of 480,000 hogs, both of which were all-time highs.

In order that both agricultural production and economic diversification would meet market demand, the county CCP committee attached extraordinary importance to survey and study of market trends, promptly mastering market information. As a result of the practice during the past several years of a policy whereby the planned economy is dominant and market regulation supplementary, market conditions have changed greatly. The county CCP committee specially organized the finance and trade organization's various units to send people out to various places inside and outside the province to survey market needs, to strengthen market forecasting, and to provide data for the guidance of production. In 1978 when export of burley tobacco was slack and the county was preparing to cut back on production, a survey showed that in some parts of the country sales were brisk, so they revived development of burley. In 1981, not only did they sell all the burley in inventory but also concluded agreements with several tobacco plants in other provinces to sell them burley in 1982. For many years numerous places have reported shortages of nonstaples such as gluttinous rice, sesame seeds, and gaoliang. The county CCP committee told this news to production teams and peasants to encourage the peasants in economic diversification. As a result of 3 years of efforts, supplies of nonstaple grain and oil have gone from little to much. In 1981, quantity of gluttinous rice procurement rose from the 130,000 jin of 3 years previously to 2.49 million jin; quantity of sesame seed procurement rose from 10,000 jin to more than 250,000 jin; and quantity of gaoliang procurement rose from somewhat more than 800,000 jin to 10 million jin. From the increase in output of gaoliang alone, 6 million jin of spirits could be distilled, providing the state with 1.48 million yuan in increased revenues. Increases in outputs of nonstaple grains and oils also promoted development of the food industry, enlivened markets, and improved the livelihood of the people.

BRIEFS

WATER STORAGE UP--Mianyang Prefecture has taken firmly in hand the restoration of projects destroyed by water, has enhanced project management, and has bolstered its ability to store and conserve water. At present, water storage in water conservancy projects of all kinds amount to 1.428 billion cubic meters, an increase in water storage of more than 80 million cubic meters over the same period last year and two percent more than plan, creating conditions for greater growing of paddy rice this year. As a result of several flood disasters last year, projects at 25,332 locations in the prefecture were destroyed and electromechanical equipment providing irrigation at 1,621 sites was destroyed. In order to repair and restore to operating the projects destroyed by flooding, since last fall, prefectures and counties (or municipalities) have worked to strengthen leadership, have sent personnel to sites to conduct inspections, have formed different categories of units, and have done overall planning for prompt organization of the masses to conduct rush repairs. Each county and municipality also focused on the new situation of promoting various forms of agricultural production responsibility systems, changing from the past practice of investing labor to investing funds. They apportioned labor according to the irrigation area and used cash to settle accounts, thereby hastening the pace of restoration of the projects damaged by floods and assuring project quality. During last winter and this spring, the prefecture worked at a total of 20,000 different sites, completing work at more than 14,000 of them. At the same time, all jurisdictions further strengthened and perfected water conservancy management responsibility systems, and adhere to centralized control of production teams over water, water being released by "a single source." They also equitably resolved compensation for personnel charged with releasing water, and satisfactorily handled the contradictions between "doubly contracted" fields [fields for which peasant households were responsible for both fixed output quotas and full task completion], and water stored in ponds and reservoirs. [Text] [Chengdu SICHUAN RIBAO in Chinese 4 Mar 82 p 3] 9432

RESTORED IRRIGATION PROJECTS--Projects destroyed by flood waters in Dujiangyan irrigation areas have been virtually all restored. During the exceptionally great floods of mid-July last year, projects at a total of 2,078 places in the Dujiangyan irrigation area were destroyed. After the flood, the broad masses of cadres, people and employees of management departments in the Dujiangyan irrigation area bent every effort to rush repairs on some of the urgently needed projects to assure the irrigation of spring-sown crops and water for industrial use. Beginning in mid-November last year, the large number of projects yet to be restored began to be repaired one after another. The Dujiangyan Management Bureau and subordinate management departments organized work teams to go into work areas to assist with the work. In a race against time, many civilian workers took no vacation at new year's time, and the projects proceeded very rapidly. Now, 1,803 projects in the Pingyuan irrigation area of Chengdu that had been destroyed have been fully restored, and restoration of the Mianyang, Longquanshan and Heilongtan irrigation areas in the hills has been largely completed. BRIEFS

PLASTIC MULCH COTTON GROWING--In 1981, 50 farms in the Xinjiang state farm and land reclamation region used plastic mulch in growing cotton on 20,000 mu. Yields of ginned cotton averaged 160 jin per mu, double the average yield per mu in the reclamation area as a whole, for an increase in earnings of 1.2 million yuan. Two years of production experience have shown that use of plastic mulch in growing cotton makes full use of solar energy, improves the ecological environment of cottonfields, regulates the physical and chemical properties of the soil, promotes microbiological activity, can increase ground temperatures, conserve moisture, reduce damage from alkalinity and salinity and control weed growth, promote cotton growth and development, achieve advanced ripening, and increase output. IMPORTANCE OF EARLY RICE CROP UNDERLINED

Hangzhou ZHEJIANG RIBAO in Chinese 16 Mar 82 p 1

[Article: "Provincial CCP Committee Comrades in Charge Question Agriculture Experts on How to Make Full Use of the Role of Science and Technology in Grain Production. Experts Hope that Leaders on All Levels Will Attach Great Importance to the Required Grain Growing Area, Particularly the Early Rice Crop Area, Will Attach Great Importance to an All Around Linking of Measures to Form a Coherent Whole to Increase Output, and Will Take Them Firmly in Hand as Measures For Making Breakthroughs"]

[Text] Zhejiang Provincial CCP Committee secretary and deputy provincial governor, Chen Zuolin [7115 0155 7207] questioned agricultural experts on 13 March on how science and technology could be relied upon to win bumper grain harvests this year. Twenty experts from the Provincial Academy of Agricultural Sciences, Agricultural University, and the Provincial Department of Agriculture gathered together in the same room with comrades in charge at the Provincial CCP Committee where they spoke with fervor and assurance, putting forward quite a few good ideas and suggestions.

Also participating in the discussions were comrades in charge at the Provincial Science Commission, and the Provincial Agricultural Commission.

In a statement, the experiments noted that in Zhejiang Province with a large population relative to available land, grain production must be taken very very firmly in hand. Adaptation of general methods to local situations for the promotion of "a multiple crop system" and a series of corresponding farming techniques are major reasons for the province's steady increases in grain output, and it is necessary to persevere in doing things this way in future. Everyone acknowledged that even in the northern part of Zhejiang Province, where more than two crops can be grown but where the growing of three would be somewhat critical, through the readjustment of crop varieties and patterns, high yeilds from three crops could still be won.

The experts pointed out that in order to make the most of Zhejiang Province's advantages for grain production, it is particularly necessary to assure the early rice crop sowing area. This is because scientific analysis shows that 70 percent of rice output is formed following heading. The early rice crop heads in July, which is precisely the month in which solar radiation is greatest in the province, helping the buildup of material through photosynthesis. Therefore, the early rice crop has become Zhejiang's dominant crop. We must use all available means to grow well and grow sufficient early rice.

In the course of discussions, the experts raised a dissent to the view that "this year's grain production lacks the means for breakthroughs and that hopes for increased output are not great." They said that means for breakthroughs cannot exist every year; however, every production team has weak links in production. At the meeting, the experts enumerated numerous effective technical measures for overcoming these weak links. The deputy director of the Provincial Academy of Agricultural Sciences, Dong Shijun [5516 0013 6874], said that some people regard the summarization and promoting of some existing measures for increasing yields as so much "gleaning of sesame seeds," which they do not think much of. In actual fact numerous breakthrough results both domestically and in foreign countries have been obtained through an all around coherent linking of science and technology. If only we will take firmly in hand existing measures for increasing yields and give attention to all around application of their mutually complementary dialectic relationship, the "sesame seeds" can turn into "watermelons." Experts at the meeting unanimously acknowledged that attention to coherency in existing techniques can effectively overcome, one by one, the weak links in increasing agricultural output, and this is a breakthrough measure in itself for grain production in Zhejiang Province this year. It is hoped that leaders at all levels will fully recognize this, and conscientiously take it in hand.

ATTENTION GIVEN TO FEED POLICIES IN HOG RAISING

Hangzhou ZHEJIANG RIBAO in Chinese 16 Mar 82 p 1

[Article by Provincial Government Investigation and Research Office, Provincial Agricultural Commission, and Provincial Finance Department Operated Investigation Unit: "After Contracting Work Tasks to Individual Households How Can Hog Raising Feed Policies Be Implemented?"]

> [Text] Editor's Note: In some of the communes and brigades in Quzhou Municipality that have instituted the contracting of work tasks to individual households, while further perfecting agricultural production responsibility systems, the work of instituting hog quota purchase tasks and hog raising feed policies in individual households has been given attention. A briefing is given here for the reference of all jurisdictions on how communes and brigades in that municipality implemented hog raising feed policies.

The Method Used In Xiazhang Commune Was to Make Livestock Feed Grain a Part of Grain Payment Quotas, Recovering It From Contract Fields

1. Stable Livestock Feed Grain Policy. When a commune member sold a porker 1 jin of feed grain was allowed for every jin gross weight. To raise a sow required about 200 jin of feed grain for an entire year, which was provided by the collective.

2. No limit on number that may be raised. Year-end settling of accounts was done on the basis of the actual number of jin of porkers sold (as determined from coupons issued by food companies at the time of purchase), and the number of sows raised.

3. Advance setting of livestock feed grain. When contracting land, livestock feed grain, state requisition procurement, and collective withholdings were all assigned to households as part of their payment tasks, production teams making centralized settlement of accounts at year end. At the time of settlement of accounts, feed grain that commune members should receive according to policy regulations was offset against quotas they were to pay.

The Method Used by the Jujia Production Brigade in Lantang Commune Was to Apportion Livestock Feed Grain and Live Hog Raising Quotas on the Basis of Contracted Amount of Cultivated Land. They Made Three Stipulations Guaranteed to Remain Unchanged for Three Years as Follow:

1. For each fattened hog sold, the collective provided a bonus of 300 jin of livestock feed grain. For each sow raised, an annual bonus of 300 jin of Livestock Feed Grain was Given.

2. For every 2 mu of cultivated land contracted for, one porker had to be sold to the state or one sow raised.

3. On average, for each mu of cultivated land contracted, 150 jin of livestock feed grain was apportioned. At the time of final settlement of accounts at year's end, if live hog raising quotas had not been fulfilled, 18 yuan in cash was deducted per head by the production team (i.e. the price difference between 300 jin of paddy rice at the unified grain procurement price and the increased grain price).

This year this brigade has fixed a hog raising quota of 513 head for its 1,026 mu of land, and a sale quota of 400 head. This will assure overfulfillment of quota.

If at the Time of Instituting a Responsibility System Contracting Work Tasks to Individual Households, What Can Be Done If Hog Raising Feed Policies Were Not Instituted at the Same Time? The Method Used by Zhanjia Production Brigade Was As Follows:

1. On the basis of average amount of feed grain provided commune members during the past 3 years the amount of livestock feed land that should be apportioned to each commune member by the production team was calculated. This was converted to a total of 600 mu of livestock feed land for the brigade as a whole, which was contracted among each hog raising household.

2. On the basis of average yields of grain per mu during the last 3 years for the brigade, a yield of 1,400 jin per mu of livestock feed land was set, 100 jin of which was agricultural tax.

3. Set hog raising quotas on the basis of output of livestock feed fields. They set 1.5 jin of unhusked rice for every jin gross weight of live hogs sold, and 450 jin of unhusked rice per sow per year. Using this standard, for each mu of livestock feed land, 860 jin gross weight of porkers should be sold to meet live hog sales quotas.

4. Live hog quotas procurement tasks and livestock feed fields were both contracted to individual households for fulfillment, final settlement of accounts being made at year's end. If live hog sale quotas were not met, for each 100 jin of feed grain, the production team collected 6 yuan from the commune member.

Agreements were signed between production teams and commune members with the aforestated stipulations to remain in force for a period of 3 years.

The Method Used by the Shangdamen Production Brigade of Huayuan Commune Was As Follows: Simultaneous with the Contracting of Responsibility Fields and Grain Ration Fields, Livestock Feed Fields Were Designated

1. Fixing of Hog Raising and Selling Tasks. The average gross weight for hogs raised by commune members during 1979 and 1980 at the time they were taken out of inventory was used as a quota for commune member hog raising this year, and assigned to individual households (Households new to hog raising used self assessment and public discussion for their hog raising quotas). Production teams signed contracts with hog raising households setting sales quotas guaranteed without change for 3 years.

2. Fixing of livestock feed grain. On the basis of the hog raising policy originally set by the production team, livestock feed grain for the year as a whole was calculated. In order to encourage commune members to raise more hogs, an additional 20 percent of reserve livestock feed grain was added as the total livestock feed grain for 1982, for planned implementation in each individual household.

3. Fixing livestock feed fields. On the basis of the total amount of livestock feed grain needed for production team distribution to commune members for their hog raising tasks, and on the basis of comparative grades of land, simultaneous with designation of grain ration fields and responsibility fields was the designation of livestock feed fields for individual households. Generally 1 fen or 1.5 fen of land per porker was allocated, and 1.5 to 2 fen per sow.

4. Year-end accounts settlement. Settlement of accounts for sows was done on the basis of actual numbers raised. For porkers, commune members settled accounts with production teams on the basis of coupons issued at the time live hogs were sold. Those who overfulfilled quotas were paid 20 percent from reserve livestock feed grain. Those who did not fulfill quotas returned to production teams the livestock feed grain (including reserve grain). However, if output fell as a result of disasters and return of livestock feed grain caused hardship, 5.80 yuan in cash for each dan of unhusked rice could be returned.

After this production brigade adopted the aforestated method, the enthusiasm of commune members for hog raising was aroused. At the end of 1981, the number of household raised live hogs in inventory rose from 336 head for the same period in the previous year to 392 head, an increase of 56 head.

BRIEFS

SPRAY IRRIGATION OF CASH CROPS--Spray irrigation techniques began to be promoted in Zhejiang Province in 1975, and now 71 counties (or municipalities) have spray irrigation equipment for the spray irrigation of an 830,000 mu area, more than 690,000 mu of which grows economic crops. It has been estimated that with the development of spray irrigation for economic crops, yields have increased by a general 15 to 40 percent. Annually the province as a whole has a 30,000 dan increase in harvests of dry tea, a 200,000 dan increase in citrus fruits, a 6,400 dan increase in silkworm cocoons, an 11,000 dan increase in cotton, a 150,000 dan increase in sugarcane, and a 5,600 increase in luoma [4820 7802] for a 25 million yuan increase in economic income. Spray irrigation is a new irrigation technique. Not only does it save labor, save water and take up less ground space than the usual ground surface irrigation, but irrigation is even, and it is possible to maintain the granular structure, proper moisture, fertility and ventilation of the soil to help crop root development and absorption of fertilizer and water. In addition crop leaves are washed, which helps in their respiration and photosynthesis, making it possible for the new to supersede the old. It also plays a role in prevention of certain diseases and insect pests; consequently results in increased yields are outstanding. [Text] [Beijing ZHONGGUO NONGMIN BAO in Chinese 4 Apr 82 p 2] 9432

TITLE: "Analysis of Spike and Grain Characteristics of Rice Plants of Different Effective Number of Tillers"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 2, 8 Mar 82 pp 1-3

ABSTRACT: For the purpose of clarifying the relationship, if any, between the characteristics of the spike and the grain and the number of effective tillers on a single rice plant, rice plants with less than 4 tillers beyond the main stem were studied in 1980 with the late rice and in 1981 with the early rice. Under the condition of dense planting (25 jin/mu of seeds for early crop and 15 jin/mu for late crop) the main stem appears to dominate as the producer while the tillers are few and weak. Small plot experiments were carried out to compare plants of a stem and tiller ratio of 1:2.8, 1:1.75, and 1:1.44. Under identical conditions of water and fertilizer applications but different transplanting densities, the yield was found to be the highest when the stem-tiller ratio was 1:2.8 with only 3 seedlings transplanted in a hole. In plots of 9 seedlings in a hole and 6 seedlings in a hole, the number of tillers was reduced because of crowding and the yield was lower as well.

TITLE: "High Yield Experience From Early Planted Summer Soybean in Low Latitude Regions"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 2, 8 Mar 82 pp 7, inside back cover

ABSTRACT: An experiment was conducted in a field of 1.066 mu in the summer of 1981 to study the high yield principle of cultivating soybean under the ecological condition of the low latitude region of the south, such as Zhanjiang. The field produced an average of 404.7 jin/mu. Aside from using a superior breed, adopting a reasonable density of plants, and carrying out the scientific management method of promoting as well as controlling plant growth, it was discovered that in order to obtain a high fruiting rate, planting should be suitably early to utilize the light and temperature advantages. It is important that the pod formation and ripening stage should be in Jul-Aug with intense solar radiation and the longest daylight hours. This high yield experience is described in some detail.

TITLE: "A Method of Fertilizer Application for High Yield Rice By Mainly Adjusting the Soil Nitrogen Supply Index"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 2, 8 Mar 82 pp 19-22

ABSTRACT: Based upon the soil nitrogen supply indices previously obtained (see GUANGDONG NONGYE KEXUE No 6, 81 pp 32-35 and No 1, 82 pp 27-30) the authors conducted an experiment in 5 types of soils to study the use of adjusting and controlling the soil nitrogen supply index as the major principle of applying fertilizer for high yield rice. According to a previous experiment in Chaoshan Prefecture, regardless of the nature of the soil, if the yield is to be about 900 jin/mu, the soil nitrogen supply index in the various stages of growth of the rice plant must reach about the same level. With this experiment, carried out in the spring of 1964-65 and in the winter of 1979-81, the index was predetermined to be 17.20 jin/mu. Throughout the growth and development period, the soil was tested to obtain the

[continuation of GUANGDONG NONGYE KEXUE No 2, 1982 pp 19-22]

nitrogen supply index before determining the need for nitrogen application 5 times in 6-day intervals. The following equation was obtained to calculate the amount of nitrogen fertilizer required, A: $A = \frac{I - (a + U)}{P \times E}$. Where I is the nitrogen supply index determined beforehand; a is the effective nitrogen possibly supplied by the soil on the 6th day after the test (estimate); U is the cumulative nitrogen absorption of the rice plant; P is the nitrogen content of the fertilizer; and E is the effective rate of the nitrogen fertilizer. In the years of 1964, 65, 80, 80, and 81, in soils of various fertility levels and under different conditions of weather, according to the experience of farmers, when this fertilizer application principle was followed, with suitable addition of phosphrus, potassium, etc. the yields were 886, 903, 941, 1033, and 996 jin/mu respectively.

TITLE: "Nitrogen-Potassium Nutritional Imbalance of Low Yield Rice and the Yield Increase Effect After Potassium Application"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 2, 8 Mar 82 pp 23-27

ABSTRACT: Due to potassium deficiency of soil and rice nutritional imbalance following an imbalance of nitrogen and potassium in the soil, red spot and sesame leaf spot [Helminthosporiose] diseases have occurred in the various rice producing regions of China in recent years. In Meijiang Commune, the diseases often occur after tillering. Some areas of Meixian Prefecture have always had the tradition of applying 200-400 jin/mu of lime, resulting in a replacement of potassium by calcium while a surplus of calcium ion may also reduce potassium absorption of the rice plants. This paper reports the results of several experiments indicating that in potassium deficient paddy soils, when more than 15 jin/mu of pure nitrogen is applied, red and brown spot diseases will seriously occur, but if an additional 10 jin of potassium sulfate, or 5 jin/mu of K_2O is applied, the disease resistance of the rice plants will improve and the yield will increase.

TITLE: "A Promising Green Manure--Vicia Sativa L."

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 2, 8 Mar 82 pp 28-30

ABSTRACT: In 1977, the Agricultural Science Station of Yunyan Commune introduced a small amount of seeds of Vicia sativa L. Experimental cultivation and seed propagation of these 4 years have been very successful. Advantages of this green manure have been found to be the following: (1) High yield and not labor consuming: The yield of grass may reach 3 - 5 thousand jin/mu and that of seeds 120-200 jin/mu. Planting and management take 3 man-days for grass and 5 for seeds. (2) Highly effective as fertilizer and capable of improving soil: Tender leaves are easily decomposed and the roots have many root nodules; (3) Drought resistant, broadly adaptable, and subject to very few pests; (4) Rich protein and starch containing seeds very good as a swine feed: Leaves and seeds of this species contain a small quantity of cyanate; therefore, they must be cooked before feeding them to animals.

TITLE: "Yield Structure and Adjustment and Control Technique of Early-Xian-233"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 10 Apr 82 pp 1-4

ABSTRACT: Early-xian-233 is an intermediate ripening breed bred out in 1978 by the Breeding Group of Fujian College of Agriculture through hybridization of Zhenlong-410 and Shilunbang before back-crossing with Zhenlong-410. It participated in the provincial early rice region experiment project in 1980 and 81 and demonstrated various degrees of yield increase over several local breeds. In 1981, 300 thousand mu of it were extended throughout the province. The author and colleagues carried out a cultivation experiment early in 1981. The yield structure of 36 paddies of varying yield levels and the fertilizer application and planting density data of this experiment are reported in the paper. The paper also contains such information as the effects of potassium fertilizer applications, the growth and development periods of different seeding and transplanting dates, the effects of low temperature in May 81 on spike development, etc.

TITLE: "Preliminary Understandings Regarding Triple-crossed Hybrid Rice"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 10 Apr 82 p 5

ABSTRACT: In the recent 3 years, triple-crossed hybrid rice has been cultivated in Fujian in large areas. It appears to be high yielding in seed propagation and the hybrids are highly adversity resistant. According to the statistics of the provincial Department of Agriculture, the acreage has been enlarged from the 200 thousand mu of 1979 to the 830 thousand mu of 1981. The experiment of Sanming Prefecture Seed Company in 1979 proved that the yield of the triple-cross(V_{41}A x Zhenxian-97)F_1 x IR_{661} is higher than the single crosses of its own group and that of several other breeds. In the paper, the author suggests that because of the genetic characteristics of the triple-cross, attention should be given to the following: (1) The F_1 sterile line must be completely sterile; (2) The stalk height of the restorer line must be similar to those of the sterile line and the temporary sterile-free line; (3) At least one of either the sterile line or the temporary sterile-free line must have good blooming habit; (4) Based upon the breeding target, all parents must be selected for the capability of complementing one another in the adversity resistant characteristics and the yield structure factors if the expected results are to be obtained.

TITLE: "Selection Breeding and Utilization of the Late-xian,Jinnanwan"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 10 Apr 82 pp 6-8

ABSTRACT: Jinnanwan is a new, typically late intermediate-ripening breed of late xian rice bred out in the early 70's. It has been extended to 740 thousand mu in the 2 prefectures of Jinjiang and Longqi to result in a total increase of more than 20 million jin of rice production. In the spring of 1971, F_2 materials were introduced from South China College of Agriculture in Hainan Island and were propagated twice in the south before being named Jinnanwan in the autumn of 1973. Its growth and development period is about 155 days but its daylight requirement is strict. When it is seeded in late May or early or middle Jun to be transplanted in early Aug, it will always begin spike evolvement in the middle of Sep but its total growth and development period may be affected by conditions of light and temperature of different years and by such factors as fertilizer managment. Its yield is 5-7 percent higher than farm breeds. Its resistance to lodging and cold wind is high. In cultivation, it should be seeded at a proper time. At transplanting,the seedlings should be 60 days old. Its tillering capacity is medium strong; generally with 7 seedlings in a bundle in spaces of 5 x 4 or 6 x 4 cun,the density is the most suitable. Seeds shed relatively easily during ripening time. Irrigation should cease one week before it is ripe and harvest should be fast.

TITLE: "Experimental Cultivation of Weilaimusi Soybean"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 10 Apr 82 pp 12-13

ABSTRACT: Weilaimusi [Williams ?; the name indicates its Western origin] soybean was introduced to the institute in 1980 and 2.5 mu of it was cultivated in the spring of 1981. The average yield was 304 jin/mu; the average yield of the high-yield cultivation plots reached 372-380 jin/mu, 3-5 times the yield of local soybean breeds. Preliminary observations indicate that aside from the high yield property, its stem is thick, its branches are few, its internode is short, its pod location is low. Each pod contains many beans. It is resistant to lodging and is tolerant to fertilizer. Its pest resistance is rather high. The pod does not burst open easily during the late stage. Results of experimental cultivations of past 2 years are briefly reported.

TITLE: "Problems of Direction and Strategy in Wheat Breeding"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 10 Apr 82 pp 14-19

ABSTRACT: During the previous year and one winter before that, while participating in the work of compiling and writing ZHONGGUO XIAOMO PINZHONG JI QI XIBU [CHINESE WHEAT BREEDS AND THEIR GENEALOGY] the author felt that in the past 32 years, a great deal of wheat breeding work has been carried out in China and nearly one thousand breeds have been produced. He also discovered some problems: (1) The breeding target has often been a yield of more than one thousand jin while the actual average wheat yield in China is only about 200 jin. The current change of efforts in the direction of scab resistance instead of ultra-high yield is both wise and realistic. (2) The genetic foundation of the parents has been rather limited. The number of genetic origins of the nearly one thousand breeds all over the country is only fourteen. Efforts must be made to find new sources, especially sources of rust resistant antigens. (3) The methods of breeding appear to be always the same. By learning from the USSR, back-crossing was believed to have little potential, for example. In reality, in foreign countries it is a popular method and considered to be useful

[continuation of FUJIAN NONGYE KEJI No 2, 1982 pp 14-19]

for resolving some problems. (4) There have been some domestic cooperative projects in crop breeding. For example, in the early 50's, cooperative efforts in the spring wheat regions of the Northeast were successful in controlling stem rust epidemics very quickly. At present, individual units or elements are still conducting political battles against one another and cannot get into the habit of cooperative breeding work. The paper praises the cooperative breeding project being carried out by members of the Plant Protection Division and the members of the Crop Breeding Division of the Wheat Breeding Research Office of the Institute of Rice and Wheat of the Fujian Provincial Academy of Agricultural Sciences as being a very worthy example. Following the above criticisms of the past projects, some constructive opinions for wheat breeding work of the future are presented.

TITLE: "Yield Increase Effects of Intercropping in Coastal Lands and the Cultivation Technique"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 2, 10 Apr 82 pp 20-22

ABSTRACT: The coastal region of the southeastern part of Fujian has a large population and very little land. Intercropping and collective management have; therefore, become a special regional characteristic, and many systems have been created. For example, in Jinjiang County, of the 144.8 thousand mu of peanuts, 110 thousand mu are intercropped with sweet potatoes. There is also the system of intercropping peanuts with soybeans as well as sweet potatoes to form the so-called double and triple intercropping systems. These systems are described in the paper, giving reasons for the yield increase effects of these systems. If these systems are to be successful, the selection of suitable breeds, planting all crops at a suitable time, reasonable density of plants to guarantee a sufficient number of each, and intensive management measures are essential. These cropping methods are introduced.

TITLE: "A Survey of Corn in North China"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 1, 17 Jan 82 pp 1-3

ABSTRACT: From 25 Aug to 12 Sep 81, the Chinese Academy of Agricultural Sciences organized a team of 25 scientists and teachers to investigate regions of Hebei, Henan, Shaanxi, Shanxi, Shandong, Tianjin, and Beijing, emphasizing on the cultivation condition of corn. The team discovered that these 7 provinces and cities constitute one of the major corn producing regions of China, with a total of 125 million mu of corn acreage, an increase of 80 percent compared with the time just after the liberation. The yield now varies from 6 hundred jin to close to one thousand jin/mu, except for arid, damp, and saline fields where the yield is less than 200 jin/mu. Corn is intercropped in wheat fields or planted after the wheat harvest; both systems were found to have advantages and disadvantages. The ratio of hybrid corn was found to vary from 75 to 96 percent but the majority of the hybrids were still the less than economically favorable single crosses. The target of the breeding work has been properly determined to be resistance to 2-3 locally predominant pests and suitable for wheat fields. The major problem was found to be breed impurity, resulting in yield reduction of 21.4 percent in some cases, virtually wiping out the advantage of heterosis utilization.

TITLE: "Cultivate Strong Early Rice Seedlings With 3-Intensive Technique"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 1, 17 Jan 82 pp 10-11

ABSTRACT: For the purpose of preparing for meeting the urgent needs of agricultural technology by production teams and farming households after the implementation of production responsibility system in rural villages, the Nan county departments of agricultural technology located on the lakeshore of Dongtinghu organized learning classes in 1981 to bring scientific seedling cultivation techniques to the farming masses. The emphasis is on the 3-intensive technique, i.e. intensive leveling of seedbeds, intensive planting procedure, and intensive management system. The rate of strong seedlings is raised from the 61 percent of 1980 to 68.8 percent. These good and strong seedlings guarantee the acreage and planting density of early rice and there has been a yield increase in every commune of the county. From the 430 thousand mu of early rice in the county, the total yield is 307,310 thousand jin, amounting to an increase of 19.7 percent over the yield of 1980. Details of this successful seedling cultivation technique are described.

TITLE: "A National Survey of Cotton Breeds"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 1, 17 Jan 82 pp 18-19

ABSTRACT: For the purpose of clarifying the conditions of selection breeding of cotton and the extension of superior breeds in the major cotton-producing provinces of China, the Cotton Research Institute of Chinese Academy of Agricultural Sciences and the Bureau of Seeds of the Ministry of Agriculture organized a survey team, which was divided into the east and the west sections. From 9 Aug to 2 Sep 81, the team visited 16 scientific research units, 27 provincial and prefecture seed companies, 12 seed farms, 19 rural cotton breeding bases, and 6 textile fiber inspection units in Hebei, Henan, Shaanxi, Shandong, Jiangsu, Hubei, Hunan, Jiangxi, and Shanghai. According to preliminary statistics, there are 22 breeds bred out in China that have been extended to over one million mu. In all the areas visited, these breeds are rapidly replacing breeds introduced from foreign countries. The most outstanding one is Lumian No 1. Last year, the area of its extension reached 18 million mu. Aside from the achievements and experiences of cotton breeding and breed extension, the paper also suggests the following: (1) Strengthen national cooperation in cotton breeding work; (2) Strengthen theoretical research; (3) Emphasize improvement of fiber quality; (4) Strengthen breed certification, regionalization, propagation, and extension work.

TITLE: "High Yield Technique and Principle of Dry Cultivation of Paddy Rice"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 4, 17 Apr 82 pp 4-5

ABSTRACT: The dry cultivation of paddy rice technique began to be studied and experimented in 1973 and since then it has been extended to some areas of North China. Due to the fact that it is suitable for the weather condition of spring drought and summer waterlogging of North China and its characteristics of saving water, labor, and fertilizer and convenience for machine cropping, the acreage is being enlarged year after year. In 1981, there was a drought in Beijing, the acreage reached 90 thousand mu, amounting to 1/10 of the total rice acreage in the city. In Japan, transplanted paddy rice has a reported highest yield of 1,753.6 jin/mu but only 1,350 jin/mu for dry seeded paddy rice. In China, in years of 79-80 there have been reports of 1,200 jin/mu yield of dry seeded paddy rice. From the experimental field of the institute, the highest yield is only 981.7 jin/mu (1975) however. Various efforts and experiments in 1979 and 1980 to cause the yield of the dry cropping technique to reach or surpass that of the paddy technique are reported. The technique of reducing the density to promote tiller spikes appears to be promising. More work is needed to find the optimal management of fertilizer and water.

TITLE: "Several Problems in Good Cropping of Hybrid Paddy Rice"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 4, 17 Apr 82 pp 6-9

ABSTRACT: At present,there is a steady development of hybrid rice culture in China but in production there remain the problems of simple grouping, overly long growth and development period, poor adversity resistance, and low and unstable yield of seed propagation. It appears that whenever the scientific principle of using groupings suitable for a particular locality is adhered to, a greater yield increase result is obtained. According to the statistics reported at the South China Hybrid Rice Survey Conference in Yueyang of Hunan Province in Dec 81, the acreage of groups having good resistance to local pests has been steadily and quickly enlarged and that of other groups shrunk to the extent the lost from diseases and pests has been effective lessened. This paper reports various scientific experiments and production experiences designed to overcome the aforementioned problems so as to guarantee a stable extension of hybrid rice culture. There is no mention in the paper in specific words that it is in fact a brief summary of the conference mentioned above.

TITLE: "New Progress in the Research on the Utilization of Wild Cotton: Interspecific Hybrid of Upland Cotton and Gossypium anomalum"

SOURCE: Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 4, 17 Apr 82 pp 17-19

ABSTRACT: Taxonomically speaking, the major cotton breeds used in production at present in China are all bred out from upland cotton, through artificial selection, hybridization, and cultivation. Due to their limited genetic origin, it is rather difficult to produce outstanding new breeds of comprehensive characteristics. In the future, as the 4-modernization construction progresses, cotton breeds will have to be not only high and stable yielding, but also suitable for mechanical cropping, highly resistant to diseases and pests, and low cost and they must also produce quality cotton fiber suitable to weave into mixed fabrics and seeds of high oil and protein contents suitable as human food as well as animal feed. In order to meet these breeding requirements, distant hybridization is becoming necessary. In the last 3 years, with the help of related organizations, more than 10 wild cotton species were introduced from foreign countries. Of these, G. anomalum is of African origin. So far, one interspecific hybrid of upland cotton (Henan-79) and G. anomalum has been obtained. This experimental breeding process is briefly reported.

I. GENERAL INFORMATION

CHEMICAL FERTILIZERS HELP PREVENT, CONTROL WHEAT FUNGUS

Beijing RENMIN RIBAO in Chinese 30 Jan 82 p 2

[Article by Liu Qingcheng [0491 1987 1004], Xu Yulan [6079 3768 5695] of the Soil Fertility Institute, Chinese Academy of Sciences: "Why Some Chemical Fertilizers Can Prevent and Control Rhizoctonia of Wheat"]

[Text] Rhizoctonia of wheat is a type of disease of the roots of wheat infected by fungus. Because the roots of wheat are damaged, the upper part of the wheat plant cannot receive a sufficient supply of moisture and nutrients. This causes the thousand grain weight of wheat to drop and sterile white spikes emerge. Generally, the yield drops by 20 to 30 percent and the yield of seriously affected plants drops by 60 to 70 percent, with some perhaps even producing no yield. This type of disease has been discovered in all major wheat producing nations in the world. It has occurred in 17 provinces and cities in our nation, most seriously in Shandong and the Hexi Corridor in Gansu. The pathogen in the remnants of diseased plants is spread by the soil and, up to now, appropriate ways of prevention and control have not been found.

Starting from the 1950's, foreign nations have started from the viewpoint of nutritional science and have compared the effects of ammoniacal nitrogen and nitric nitrogen upon rhizoctonia of wheat. In the 1970's, China's agricultural science workers also observed that certain chemical fertilizers have the effect of preventing and controlling rhizoctonia of wheat. A lot of work has been done. We began with different varieties of chemical fertilizers and studied the function of different varieties of chemical fertilizers in preventing the disease. We discovered that the effectiveness of nitrogen and phosphorous fertilizers with the same amount of effective nutrients was very different in preventing the disease. In pot cultivation experiments, the effectiveness of ammonium sulfate and urea was compared. Ammonium sulfate applications could lower the index of the wheat disease by 25 to 30 percent. When comparing calcium superphosphate and calcium-magnesium-phosphorus fertilizers, calcium superphosphate can reduce the index of the disease by 15 to 20 percent. Large field experiments also showed the same results. When the amounts of phosphorus and nitrogen in the soil were the same, ammonium sulfate treatment was visibly better than urea treatment. According to our experiments, ammonium chloride, potassium chloride, potassium sulfate, ammonia water and potassium nitrate were all effective in preventing and controlling wheat rhizoctonia to different degrees.

Chemical fertilizers are not insecticides. Why do they have a preventive and controlling effect upon root disease of the crop? This is because when chemical fertilizers enter the soil, the affect certain properties (such as the degree of acidity and alkalinity, the concentration of ions) of the soil (especially the soil surrounding the roots). The microorganisms living in the soil and the soil environment are united. Changes in the nature of the soil will necessarily affect the microorganisms either favorably or unfavorably. Wheat rizoctonia is a fungus that is relatively tolerant to alkalinity, but not tolerant to acidity. In an acidic environment, its growth is suppressed. When physiological acidic chemical fertilizers in the soil are absorbed by the root system of the crop, an acidic protective layer is formed around the root system, and this produces the preventive effect. Although calcium superphosphate does not possess physiological acidity, it does contain some residual acid which belongs to chemically acidic fertilizers. It can reduce the pathogenicity of the pathogenic microorganisms. The function of ammonia water in preventing the disease is mainly due to the ammonia fume which is bactericidal. According to our experimental observation, ammonia water diluted eight times still has a very strong bactericidal effect upon rhizoctonia bacteria. The mechanism of disease prevention of some other chemical fertilizers still requires further study.

READYING OF WATER PROJECTS FOR NEW YEAR IN FARMING REPORTED

Beijing RENMIN RIBAO in Chinese 18 Mar 82 p 2

[Article: "Solid Job Done Nationally in Winter Farmland Water Conservancy Construction. Change of Production Conditions To Win a Bumper Harvest in Agriculture This Year"]

[Text] During winter construction of farmland water conservancy, rural villages everywhere adapted general methods to local situations to construct a number of small and fully equipped projects able to provide benefits this year to improve conditions for agricultural production, creating favorable conditions to win a bumper harvest in agriculture this year. According to incomplete statistics from water conservancy units, nationally water conservancy projects of various kinds have been built at more than 300,000 sites, and both quality of construction and actual benefits have been improved over previous years.

In the wake of further implementation and perfection of agricultural production responsibility systems everywhere, enthusiasm of the peasant masses for improvements in production conditions and development of agricultural production is higher. They have urgently demanded construction of farmland water conservancy to increase ability to withstand disasters and to assure consistently high yields in agriculture. In some places practicing "double contraction" to households, commune members got together of their own free will to pool funds for water conservancy. The experience of many places last winter in the construction of water conservancy has demonstrated that all that is needed is serious attention on the part of leaders, adroit guidance according to circumstances, rational planning, policies that are right on the mark, adaptation of general methods to local situations, and striving for genuine benefits, and no matter the form of production responsibility system practiced in agricultural production, farmland water conservancy construction can be done and it can be done more solidly. Last winter Shandong Province newly increased or improved an irrigation area more than double that of 1980, and benefits from investment in water conservancy also increased. By persevering in all around planning, construction in installments, and adaptation to agricultural production responsibility systems, Jiangsu Province established various forms of farmland water conservancy construction responsibility systems, and satisfactorily handled the relationship between "centralized management" and "contracting,'" thereby arousing the enthusiasm of the masses. Work efficiency was high, quality of work good, and the pace rapid on water conservancy projects built during the winter, and 7.49 million trees were also planted in combination with the water conservancy construction for the greening of an area of 54,000 mu.

In the course of last winter's water conservancy construction, all jurisdictions showed substantial concern for proceeding from actual local circumstances in an adaptation of general methods to local situations. In view of the small amount of rainfall during 1981 and the continuation of the drought, the provinces of Shanxi, Hebei, Shandong, and Henan not only intensified management of existing project construction for active development of winter irrigation, but also focused on the need to combat drought to rebuild or build new wells, ditches, and pumping stations, and such small scale projects from which benefits can be derived during the current year, and to provide more water conservancy facilities for the spring fight against drought to protect the wheat and do spring sowing. The provinces of Sichuan and Shaanxi, which last year were severly stricken with flood and waterlogging disasters, placed the emphasis of winter construction on the rebuilding of projects destroyed by water. Last winter a workforce of 1.02 million went to work in Sichuan Province to rebuild water damaged projects at more than 10,000 places. Hanzhong Prefecture in Shaanxi Province has started work at 6,800 sites on the rebuilding of projects destroyed by water. Irrigation water is flowing already in 14 of the prefecture's 18 irrigation areas larger than 10,000 mu. As a result of various work problems during the past 2 years in Woyang County, Anhui Province, a certain amount of damage was done to projects over a wide area. During last year's winter repairs, they concentrated forces on the renovation of former water conservancy projects, practicing "one withdrawal and four returns," meaning the withdrawal from much land formerly taken, and the return to ditches, furrows for irrigation, roads, and forests. Now the former ditch, furrow, and road network has been substantially restored to provide a good foundation for combating drought and preventing waterlogging this year. In addition throughout the province each person wss aroused to plant 20 trees.

Since the beginning of the lunar new year, all jurisdictions have taken advantage of the favorable opportunity before the very busy period of spring farming to organize forces to continue construction and to wind up work on various projects. They have striven to start managing and derive benefits from every location as work is completed on it, so that the role of projects can be brought into play for this year's production.

BRIEFS

TREE PLANTING ACHIEVEMENTS--Beijing, 16 May (XINHUA)--China achieved gratifying results in the first year of its nationwide voluntary tree planting campaign. According to data supplied by the Ministry of Forestry, some 1,100 million trees were planted last spring to meet people's tree-planting quotas. In addition, some 35 million mu of land was afforested, 3,000 million trees planted around houses and along roads, rivers and lakes and 2.8 million mu of saplings grown. A leading comrade of the ministry told XINHUA that, while the achievement is significant, there are still some problems needing to be resolved. Among them are an inadequate supply of saplings and lack of attention to trees after planting. [OW250301 Beijing XINNUA Domestic Service in Chinese 0704 GMT 16 May 82]

HE KANG ON BUILDING FARM RESEARCH PROJECTS

OW191141 Beijing XINHUA Domestic Service in Chinese 1512 GMT 17 May 82

[Text] Wuhan, 17 May (XINHUA)--He Kang, vice minister of agriculture, animal husbandry and fishery, at the inauguration ceremony for an agricultural testing center of the Hubei Provincial Academy of Agricultural Sciences today, said: Our country will complete the building of a number of key agricultural scientific research projects this year. This will greatly improve the conditions for agricultural scientific research in our country.

He Kang continued: The agricultural testing center of the Hubei Provincial Academy of Agricultural Sciences is the first of a number of key agricultural scientific research projects that are being built. Still to be completed are a paddy rice research institute of the Guangdong Provincial Academy of Agricultural Sciences, a laboratory of the Soil and Fertilizer Research Institute of the Chinese Academy of Agricultural Sciences, a central laboratory of the Sichuan Provincial Academy of Agricultural Sciences, a Loess Plateau Soil Testing Center of the Shaanxi Provincial Academy of Agricultural Sciences, a central laboratory of the Xinjiang Uygur Autonomous Regional Academy of Agricultural Sciences, the Agrobiological Genetic Physiology Research Institute of the Jiangsu Provincial Academy of Agricultural Sciences and the Soybean Research Institute of the Jilin Provincial Academy of Agricultural Sciences. Six of the nine key agricultural scientific research projects will engage in scientific research, with the stress on serving agricultural production, while the other three will serve agricultural production, with the stress on scientific research. These projects have been or are being built with investments from the state and from localities in order to improve material and technical conditions for agricultural scientific research and to meet the requirements of agricultural modernization in our country.

After their completion, these key agricultural scientific research projects will do work for the modernization of agricultural scientific research in our country. On the basis of further summing up experience in building agricultural scientific research projects, the Ministry of Agriculture, Animal Husbandry and Fishery will make concerted efforts together with various local governments to improve scientific research conditions and technical equipment of our country's agricultural scientific research units by stages and in groups so that they will measure up to advanced world levels.

FARM MACHINERY ENTERPRISES INCREASE EFFORTS TO MEET MARKET DEMANDS

Beijing BEIJING RIBAO in Chinese 14 Feb 82 p 1

[Article by Shi Yuandan [0670 0337 2481]: "The Enterprises of the City's Farm Machinery System Adapt to the New Situation in the Farm Villages--They Exert Efforts to Increase Products that Meet Market Demands and Small Farm Machinery"]

[Text] The enterprises subordinate to the city's Farm Machinery Bureau have conscientiously implemented the policy of readjustment, adapting to the new situation in the farm villages after implementation of the production responsibility system. They have exerted efforts to increase the production of products that meet market demands and small farm machinery and tools that are urgently needed in the farm villages. This has created a new situation in production. In January, the total production value of enterprises under the direct jurisdiction of the bureau increased 20.7 percent over the same period a year ago.

During the second half of last year, the enterprises subordinate to the Farm Machinery Bureau underwent reorganization and readjustment. To open up sales for their products, each unit improved quality on the one hand and developed sales and services on the other. At the beginning of last year, the Hand Tractor Plant only had an order for three units. This year, because the quality was improved and because the plant's representatives went deeply into the communes and brigades to offer services, the plant won the trust of the users and, at the beginning of this year, the orders jumped to more than 2,000 units. In January they organized forces to increase production and greatly hastened the progress of assembly. To deliver the products to the users in time, they organized manpower during the spring holidays to help the railroad department load and transport the units. By the first day of the Chinese New Year, 200 units had already been shipped.

Some enterprises of the farm machinery units also exerted efforts to produce more small farm machinery and accessories which were deficient in the market while they completed state plans. The City Power Machinery Plant manufactured metallic chicken coops for commune members engaged in chicken and egg production. The coops were welcomed by commune members.

PROVINCIAL TIDELAND RECLAMATION 1981 GAINS NOTED

Fuzhou FUJIAN RIBAO in Chinese 6 Feb 82 p 1

[Article by Zhao Erkang [6392 1422 1660]: "Tideland Reclamation Area in Province Tops 1 Million Mu"]

[Text] Last year our province's reclamation of tideland in coastal areas achieved new successes, the provincial plan to enclose 60,000 mu of land and reclaim and cultivate 10,000 mu of land has now been fulfilled or is about to be fulfilled, and at this point the area of tideland reclaimed by the province has topped 1 million mu.

Last year our country's coastal tideland reclamation work focused on projects to round off the enclosure of tideland and make use of the land for reclamation and cultivation. Its characteristics were: (1) there were many enclosure projects, in all eight; (2) the enclosures were comparatively smooth, all being successful the first time, and after the enclosures the sea walls were stable; (3) the longstanding, big, and difficult reclamation projects like the Ningde Two City and Xiapu Three Red were successfully enclosed; and (4) the rate of reclamation and cultivation was fairly fast and the economic results were great. The policy of relaxation has aroused the enthusiasm of the collective and the individual in many localities, and over 96,000 mu of tideland has been reclaimed and cultivated; according to the principle of farming on land suitable for farming, fishing in areas suitable for fishing, and extracting salt on land suitable for salt extraction, most of this land was planted to paddy rice, sweet potatoes, sugarcane, peanuts, beans, and other crops. Also newly opened were over 6,200 mu of shrimp pools and fish-rearing pools, and over 12,000 mu were used for aquatic breeding in former harbor channels and for newly built saltworks. Last year the total output value of agriculture, fishery, and salt industry in the new reclamation area reached over 13.4 million yuan, thereby supplying to the state many agricultural and subsidiary products, stimulating the market, and increasing the peasants' income.

That our province last year obtained remarkable results in enclosing tideland along the coast for cultivation was mainly because the party and government at all levels strengthened the leadership over the work of enclosing tideland for cultivation, did things scientifically, developed the role of technical personnel at water conservancy projects, strengthened the management of projects, and put into effect the responsibility system. Although weather conditions last year were detrimental to the enclosing of land for reclamation projects, with many typhoons, big floods, and unusually high tides, which posed many difficulties for the enclosure projects; under the attention of the leaders concerned, the cadres, workers, and technicians engaged in this work made great efforts together, overcame the difficulties, and finally completed successfully the work of blocking harbors and enclosing tideland. For example, in the Fuqing Keyu and Pingtan Xingfu Yang reclamation projects, before the land was enclosed, the leadership made personal on-site inspections, repeatedly studied and formulated enclosure plans, and chose the most advantageous times for blocking harbors, and as a result the harbor blocking went extremely smoothly.

EDITORIAL: STATE PLAN, GRAIN OUTPUT MUST NOT BE SLIGHTED

Fuzhou FUJIAN RIBAO in Chinese 9 Feb 82 p 1

[Editorial: "Uphold Planned Economy, Stabilize Grain Acreage"]

[Text] The "Beginning of Spring" [first solar term--5 February], has already passed and the rural communes and production teams are now getting a tight grip on the implementation of this year's planting plan. Herein lies a problem, viz, we must, according to the state plan, arrange well the acreage to be planted with grain this year.

We bring up this problem because, after various forms of the responsibility system were put into effect, some cadres and commune members seem to think that agricultural production does not need to be planned and that whatever they want to plant can be planted, so that there is a trend to further reduce the acreage planted with grain.

Everybody knows that the "Resolution on Certain Questions in the History of Our Party Since the Founding of the PRC," adopted by the 6th Plenary Session of the 11th CCP Central Committee, pointed out: "It is essential, on the basis of the public ownership of the means of production, to put into practice a planned economy and at the same time to give play to the supplementary role of market regulation." No matter what form of the responsibility system is put into practice, the agricultural economy must likewise put into practice a planned economy and must likewise make the planned economy primary and market regulation supplementary, and it definitely cannot disregard the state plan and develop freely. This indicates that in the current implementation of the planting plan we must accept the guidance of the state plan. The state must respect the right of the production teams to act on their own and must respect the interests of the peasants, and the peasants must act within the framework of the state plan. There are many people and little land in our province, with a provincewide per capita average of only 7 or 8 fen of cultivated land. In the past several years, although grain output has increased in successive years, generally speaking, the level of grain production is still relatively low, and, compared with the speed of the development of the national economy and the requirements for continually improving the people's life, it is still very unsuitable. The average per capita amount of grain is relatively small, and the arrangements in various aspects are relatively tight. Over the last 3 years, the internal structure of our province's agriculture has been reformed, and already the acreage planted to grain has been adjusted downward by over 2.2 million mu. This readjustment was completely necessary, and the economic effect has been marked. Now, the grain acreage must be stabilized and it cannot again be reduced. If the acreage were to again be reduced, this would cause a reduction in grain output, which would affect the stability of the state, the people's livelihood, and society. Leaders at all levels must be clear-headed on this point, and they certainly cannot treat lightly this important matter which affects the whole situation!

In stressing planning now, we do not want to change the policies since the third plenary session, and also we do not want to not engage in a diversified economy or to change the internal structure of agriculture. Our policy is still to not slack off in grain production while vigorously developing a diversified economy. Therefore, it is necessary to reform the internal structure of agriculture, and on this point no vacillation is allowed; but the total output of grain must increase on a stable basis, and we must insist upon this point. Between the two points there truly is a contradiction. Can the contradiction be resolved? It can. The fundamental orientation for resolving the contradiction lies in the mountains and the sea. Our province has many mountains and a vast sea. The mountains are "gold mountains" and the sea is a "silver sea." In our province, to study well the "mountain and sea classic" is a big question of a strategic nature. That is to say: in order to develop economic crops and to develop a diversified economy, we must fix our eyes on the natural resources of the mountains and the sea that have not been fully utilized, and we cannot just look at the cultivated land now available. As for the economic crops on the existing cultivated land, their per unit area yield and quality should be raised, and we cannot squeeze the grainfield acreage. With the exception of city suburbs and certain economic crop areas, in all other places the grain acreage must be stabilized. Grain-producing areas must continue even more to make hard efforts to develop grain production.

We must carry out socialist, patriotic education among the peasants so that they will uphold the economy and a stable grainfield acreage. Since the third plenary session, the party and government have put into effect a series of rural policies, all of which will enrich the country and the people and all of which are in the long-term interests of the peasants. That the state considers the interests of the peasants in this way means that the peasants should fulfill their obligations to the state and make more contributions to the state and that they cannot just choose methods that are of temporary advantage to themselves and disregard the state's fundamental interests. We must educate the peasants to give consideration to the interests of the state, the collective, and the individual and, according to the state's plan, by means of contracts, do a good job of planting grain and economic crops and rationally arrange the proportion of grain and economic crops planted.

To stabilize the grainfield acreage and insure a stable output increase of grain--this is the glorious task of the great number of cadres and commune members throughout the province, and they must concentrate their energy and go all out to do a good job of spring plowing and production. At present, in many areas the work of preparing for plowing and sowing has been inadequate, not much farm manure has been accumulated, the winter plowing and soil turnover was deficient, and many water conservancy works have not been timely reconditioned. Party committees and government at all levels must really strengthen leadership over spring plowing and production, give full play to the role of rural basic-level organizations, and get a good grip on all material preparation for spring plowing and win a victory in this battle of spring plowing.

FASTER WORK IN WINTER SOIL TURNOVER URGED

Fuzhou FUJIAN RIBAO in Chinese 9 Feb 82 p 1

[Article by Chen Benxiang [7115 2609 3276] et al.: "Intensify Soil Turnover To Greet Spring Plowing"]

[Text] According to statistics compiled by the provincial department of agriculture on 5 February, winter soil turnover throughout the province has been completed on over 6.5 million mu, which amounts to 81.5 percent of the fallow fields on which soil should be turned over. This work has been done a little faster than in the corresponding period of last year, but there is an imbalance between prefecture and prefecture, between county and county, and quite a few of them are lagging behind.

In Longxi Prefecture, winter soil turnover was fairly rapid, by 18 January this work had been basically completed on the acreage--over 935,000 mu--on which soil should be turned over. After the first winter soil turnover was finished on Longhai County's scheduled 135,000 mu of farmland, a second turnover was done on 10,000-odd mu. In this county, some communes and production teams located in mountains, this year are also using the method of piling up soil walls in order to dry the soil and promote weathering; some of them are fumigating the soil in order to raise its temperature. Before the year began, Guangze, Jiangle, Ninghua, Changting, Yongding, Shanghang, and Wuping counties had basically completed the task of winter soil turnover.

The common experiences of these prefectures and counties which did a good job of turning over the soil was that before the new year began they strengthened and perfected the production responsibility system, thereby stabilizing popular morale. For example 960 of the 982 production teams in Guangze County strengthened and perfected the production responsibility system. Next, the organization of the production brigades and production teams was overhauled and consolidated and the leading groups were strengthened, and therefore the cadres dared to grasp and manage the work and were bold in providing leadership.

Jiangang and Ningde Prefectures were comparatively slow in winter soil turnover. As of 1 February, Jiangang had completed half of its soil turnover and was 20,000 mu short of the acreage turned over in the corresponding period of last year. In Fuding and Fu'an Counties of Ningde Prefecture, soil had only been turned over on about 30 percent of the required acreage. The counties which had fallen behind were Mingxi County, which has only completed one-third of the work, and Changle County, which is 10,000 mu behind what it was in the corresponding period of last year. Among the reasons for the relative slowness in turning over soil in these prefectures and counties are that the production responsibility system has not yet been implemented and that among the peasants there exists the idea of looking on and waiting: some cadres of some communes and production teams in localities where the "double contract" [system of fixing output quotas based on households and system of peasant households assuming full responsibility for task completion] system has been put into effect think that the peasants themselves will do the work of winter soil turnover and they have slackened their leadership, and in particular some of the masses think that this year is a "year with an extra spring" and a leap month of April so that the seasons come slowly and there will still be time to turn over the soil.

A comrade of the provincial agricultural department thinks that although the golden season for winter soil turnover has already been missed, to plow now will still turn over the soil in good fashion compared to the time when there is more water in the fields, because there is still a certain time left to turn over the soil and let it weather and the farmwork can be staggered. But during the current plowing, attention must be paid to deep-plowing the originally plowed layer so as to avoid turning over immature soil and thus adversely affecting the growth of early-season rice. He hopes the prefectures in which the soil-turnover rate is slow will strengthen their leadership, getting a good grip on implementing the production responsibility system, on reorganizing the basic-level leading groups and organizing the commune members to concentrate their manpower, animal power, and farm machinery and tools on the work of turning over the soil in preparation for plowing and sowing, so that the necessary conditions will be created for wresting a bumper grain harvest this year.

BRIEFS

SONGXI COUNTY RICE CROP--The peasants in Songxi County, Fujian Province, planted more than 120,000 mu of double-cropping early rice and afforested more than 33,000 mu of land this year, overfulfilling their tasks. [OW271111 Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 26 May 82]

EARLY RICE--The Fujian Provincial Agricultural Department held a meeting 10-12 May in Fuzhou, attended by directors of prefectural and county agricultural bureaus, to discuss the work of early-rice planting in the province. It was pointed out at the meeting that this year's early-rice planting plan had not been fulfilled, and that as of the beginning of summer, only 9.74 million mu had been planted, a decline of some 700,000 mu compared with the same period of last year. Under these circumstances, the meeting urged, great efforts should be made to increase the total grain output by 300 million jin this year. Among other things, it called for attention to controlling possible rice diseases and insect pests. [OW161339 Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 14 May 82]

YONGAN COUNTY FLOODS--On the evening of 10 May, Yongan County, Fujian, was hit by torrential rains and hailstorms rarely seen in many years. The waters cascading down from the mountains and spilling over from overflowing rivers inundated over 19,000 mu of rice fields, almost disrupted the harvesting of nearly 1,000 mu of vegetables, destroyed a number of bridges, highways and water conservancy facilities, tore down houses and injured or killed people and animals. In view of the disaster, leaders of county departments concerned have organized the people in the more seriously affected communes, production brigades, production teams, plants, mines and enterprises to carry out rescue, relief and repair activities. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 15 May 82]

SPRING FARMING--Fujian Province has basically completed spring farming for this year. According to agricultural departments, as of 5 May the province had planted 9.5 million mu of early rice, 526,000 mu of soybean, 1.17 million mu of peanuts and 700,000 mu of sugarcane. This year the acreage planted to early rice is more than 500,000 mu less than last year. [OW191405 Fuzhou FUJIAN RIBAO in Chinese 8 May 82 p 3]

MARINE ECOLOGICAL RESEARCH--Xiamen, 27 May (XINHUA)--Chinese oceanologists will take an active part in international academic exchanges in marine eco-system and marine environmental protection under a plan announced at a recent special committee meeting on marine ecology of the Chinese Ecological Society. According to the plan, efforts will be organized to forecast the effect of human activity on marine eco-system, carry out research on controlled eco-system and on marine artificial biology, and tap measures to protect marine organism resources. Scientists who attended the meeting in this Fujian Province coastal city called for strengthening the research of primary marine productive forces. [Excerpt] [Beijing XINHUA in English 0721 GMT 27 May 82 OW]

COUNTY RAPESEED PROCUREMENT--Ninghua County, Fujian Province, has reaped a bumper harvest of rapeseed on 59,900 mu this year. As of 18 May, the county had procured 37,000 jin of rapeseed oil. [Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 5 Jun 82]

SANMING PREFECTURE RICE--The acreage under early rice in Sanming Prefecture, Fujian Province, has been reduced by 120,000 mu because of a decision in spring to turn low-yield rice fields to the growth of single rice crops instead of double rice crops. At the same time, the prefecture's acreage under hybrid rice strains will expand from last year's 500,000 mu to more than 700,000 mu. [OW061337 Fuzhou Fujian Provincial Service in Mandarin 1120 GMT 30 May 82]

PROVINCE SUFFERS FROM OVERRUNNING WEEDS

SK200658 Lanzhou Gansu Provincial Service in Mandarin 2200 GMT 18 May 82

[Letter written to the station's editorial department by (Ge Guangxin), senior agronomist and deputy director of the Provincial Agricultural Bureau, urging all localities to conquer overrunning weeds as early as possible]

[Excerpt] The letter notes: Now our province's spring sowing and plowing are nearing successful completion and summer hoeing has already begun. Adopting effective measures as early as possible to conquer overrunning weeds to promote the growing of crop seedlings is an important task for agricultural production. Our province has more lands but fewer residents; thus, the cultivation of farmland is extensive. In each of the past years, about 10 to 20 million mu of farmland were overrun with weeds, which affected agricultural production.

The province experienced more rainfall last year. Hejing and Mudanjiang prefectures were stricken by serious floods and waterlogging, interfering with timely weeding, plowing and banking soil to the growing crops in the summer. As a result, much farmland was overgrown with weeds.

According to an investigation made by the Huanan County Agriculture Department at (Jiancaogou) brigade in (Dabalang) commune, there are 3,000 to 8,000 grass seeds on every one square meter plot overrun with weeds. Since many plots were not cultivated and many grass seeds left on land last year and the soil moisture content is good this year in most areas, grass seedlings have grown on plots cultivated at an earlier date.

In line with an investigation of wheatfields at a seed multiplication farm in Huanan County, some 530 blades of small grass have grown on each one square meter plot, weeds outnumber crop seedlings and grass seedlings are growing. If we fail to promptly adopt measures to eliminate weeds, damages this year will be more serious than last year. All localities should pay attention to it.

RICE INSTITUTE INAUGURATED IN GUANGZHOU

OW231218 Beijing XINHUA in English 1208 GMT 23 May 82

[Text] Guangzhou, 23 May (XINHUA)--An inauguration ceremony was held here on 22 May for the newly expanded Rice Research Institute under the Guangdong Provincial Academy of Agricultural Sciences.

Standing on the outskirts of the city, the Rice Research Institute has been upgraded with up-to-date apparatus. It will make researches on rice, which accounts for nearly half of China's grain output.

The predecessor of the Rice Research Institute was a rice experimental farm founded 50 years ago by famous Chinese rice expert Professor Ding Ying. The research results obtained by the institute in breeding low-stalk rice varieties have won recognition both at home and abroad. With 220 scientists and staff members, the institute will conduct research and tests for Guangdong and other southern China provinces.

The institute lays stress on research in applied techniques and development of production while strengthening studies in fundamental theories. It will help train scientists and technicians.

The institute will also conduct international academic exchanges.

It is equipped with atomic absorption spectrophotometers, apparatus for analyzing the properties of cereals and other up-to-date instruments.

Among the over 100 people attending the inauguration ceremony were Liu Xigeng, a representative of the Ministry of Agriculture, Animal Husbandry and Fishery, Fan Xixian, vice governor of Guangdong Province, and scientists and experts.

BRIEFS

PIG PRODUCTION INCREASES--According to the statistics compiled by the Guangdong Provincial Statistical Bureau, the number of pigs raised in the province in the first quarter of this year was some 21.83 million, 3.9 percent more than in the same period of last year; and the amount of pigs on hand in the first quarter of this year was some 19.35 million, 4 percent more than in the corresponding period of last year. Of these, the number of sows on hand, which were capable of breeding, was 16.7 percent more than in the same period of last year. The number of piglets on hand was 12.2 percent more than in the corresponding period of last year. The number of pigs sold in the first quarter of this year was 94,700 more than in the same period of last year, an increase of 4 percent. [HK191453 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 10 May 82]

HAINAN AGRICULTURAL LOANS--Agricultural banks and credit cooperatives in all places in the Han areas in Hainan region have issued loans to commune members to develop agricultural production. They issued loans of some 32 million yuan to individual commune members from January to April this year. This amount accounted for 55.5 percent of the total amount of agricultural loans in the same period and was 32.9 percent more than in the corresponding period of last year. With these loans, peasant households can buy seeds, chemical fertilizers, draft cattle, agricultural machinery and tools. [Haikou Hainan Island Service in Mandarin 0330 GMT 24 May 82]

HAINAN ENTERPRISES FINANCIAL INSPECTION--Hainan region has conducted a large-scale inspection of the finances of state-run enterprises in its Han areas. According to incomplete statistics, by the end of April, cases in violation of financial discipline, involving 2.494 million yuan, had been discovered and 518,000 yuan of this amount had been submitted to the treasury. This year, the Hainan administrative commissioner's office twice issued instructions on conducting a large-scale inspection of the finances of the state-run enterprises throughout the region. The regional administrative commissioner's office and all county people's governments have set up large-scale leadership groups for inspection of enterprise finances. [Haikou Hainan Island Service in Mandarin 0330 GMT 11 May 82]

SPRING-HARVESTED CROPS--All places in Guangdong Province have completed harvesting of spring-harvested crops. According to statistics, the province's total output of spring-harvested crops was 1.173 billion jin, 2.18 percent more than last year. Output of soybeans increased by 20 percent, output of tobacco increased by over 10 percent and output of vegetables also greatly increased. [HK260927 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 25 May 82]

CSO: 4007/422

BRIEFS

WINTER TOBACCO HARVEST--Nanning, 24 May (XINHUA)--The quality of the 636,600 dan winter tobacco harvested this year in Guangxi is the best ever harvested by the peasants. [OW250431 Beijing XINHUA Domestic Service in Chinese 0051 GMT 24 May 82]

SUGARCANE PRESSING--In the 1981-1982 sugarcane-pressing season, Guangxi region pressed some 4.18 million tons of sugarcane, some 830,000 tons more than in the preceding sugarcane-pressing season, an increase of 24.77 percent. The region manufactured some 490,500 tons of sugar, some 69,500 tons more than in the preceding sugarcane-pressing season, an increase of 16.5 percent. Because sugarcane production increased in this sugarcane-pressing season, sufficient raw materials were supplied for the production of alcohol. In this sugarcane-pressing season, output of alcohol reached some 11,200 tons, 41.9 percent more than in the preceding sugarcane-pressing season. [HK240354 Nanning Guangxi Regional Service in Mandarin 1100 GMT 13 May 82]

GRAIN PRODUCTION--According to a recorded talk by (Yu Yunhong), vice chairman of the Guangxi Regional Agricultural Committee, the region's total output of grain in 1981 was 1.6 times greater than in 1950, an average increase of 3.2 percent each year. Even if this is so, we must by no means disregard and relax production of grain. We must make grain production develop steadily. At present, this region has not yet solved the problem of adequate grain production. Generally speaking, to solve the problem of adequate grain production, each person should produce an average of over 1,000 jin of grain; to basically solve the problem, each person should produce an average of 800 jin. At present, each person in this region produces an average of some 670 jin of grain. With this output, the region will not be able to meet the needs in times of serious natural disasters or other emergencies. The region must therefore strive to develop grain production. [HK061501 Nanning Guangxi Regional Service in Mandarin 1100 GMT 5 May 82]

COMMERCIAL GRAIN BASES--The Guangxi regional conference on the work of commercial grain bases which is being held by the regional CCP Committee and the regional people's government opened on 8 May. The conference pointed out that, since 1980, the 150 communes in this region which have built 184 commercial grain bases, have initially achieved good results. In 1980, the majority of these communes increased production and the arable land covered by the bases accounted for 22 percent of the region's total area of arable land. These bases' output of grain was 257.94 million jin, 74 percent of the region's output of grain. In 1981, despite serious natural disasters, some communes with commercial grain bases increased production. In 1981, the arable land of these commercial grain bases accounted for 27.2 percent of the region's total area of arable land. The communes with commercial grain bases have also developed diversification. Over the past 2 years, these bases have produced 319,500 tons of sugarcane, an increase of 28.3 percent and increased the number of draft cattle by some 16,000 head, an increase of about 2 percent. The number of pigs in these bases in 1981 was 260,000 head more than in 1980, an increase of 9.6 percent. In 1981, the state invested some 56 million yuan in water conservation projects in these bases and this investiment was 46.8 percent of the total investment in water conservation projects in the whole region. [HK191333 Nanning Guangxi Regional Service in Mandarin 1100 GMT 9 May 82]

METEOROLOGICAL FORECASTS--Under the influence of atmospheric circulation, Guangxi region had natural disasters, such as hailstorms, strong wind, a spring cold wave and extraordinarily torrential rain, one after another and incurred serious losses. In the next few months, the region may possibly have natural disasters, such as drought, floods, strong wind and low temperatures. All places must make good preparations against natural disasters and do everything possible to reap a bumper agricultural harvest this year. According to the analysis of the regional meteorological department, from May to October this year, the main natural disasters will be drought, floods, strong wind and low temperatures. In May, the region may possibly have three to five hailstorms. In the second half of this year, the region may have tornados, thunder-storms in some areas and strong winds. It is estimated that between June and August this year, it will rain more in this region and floods may occur. In September and October, it will rain less in the north and the central parts of the region and there may be drought. [HK130717 Nanning Guangxi Regional Service in Mandarin 1100 GMT 7 May 82]

CANE SUGAR--Nanning, 14 May (XINHUA)--The Guangxi Zhuang Autonomous Region, a major cane sugar producer, has produced more than 500,000 tons of cane sugar, an alltime high, in the 1981-82 refining year, according to the regional light industrial department. The increase resulted from the peasants' higher enthusiasm for sugarcane planting under the responsibility system and the growth of the crop on an additional 17,300 hectares, the department said. In the current refining year, sugarcane supplied to the region's sugar refineries came to 4.24 million tons, an increase of 24.8 percent over the previous refining year, the department said. In an effort to expand the sugar refining capacity, the region has completed 12 refineries since 1978, thus adding a daily refining capacity of 7,500 tons to the total. Last year, 22 refineries went through technical transformation, adding a daily refining capacity of 4,700 tons to the total, the department reported. [OW201025 Beijing XINHUA in English 1207 GMT 14 May 82]

SUGAR PRODUCTION IN GUANGXI--Guangxi Zhuang Autonomous Region has broken historical records for sugar production. By the end of the most recent season, it had produced 500,000 metric tons of sugar. In order to expand its sugar cane processing capacity, Guangxi has built 12 new automated sugar mills since 1978. It thereby increased its daily cane pressing capacity by 7,500 metric tons. Last year the autonomous region renovated 22 automated sugar mills, increasing its processing capacity by more than 4700 metric tons. [Text] [Shenyang LIAONING RIBAO in Chinese 19 May 82 p 4]

AGRICULTURE OFFICIALS WAGE PROPER CARE FOR WHEATFIELDS

Shijiazhuang HEBEI RIBAO in Chinese 14 Mar 82 p 1

[Article: "Energetic Action in Caring for Intermediate Yield Region Wheat, Which Holds Greatest Potential for Increased Yields. Comrades in Charge at Provincial Agriculture Bureau Make Statement on Doing a Good Job of Wheatfield Care"]

[Text] Recently, comrades in charge at the Provincial Agriculture Bureau made the following remarks about the issue of doing a good job of wheatfield care.

The emphasis in wheatfield care should currently be placed on care of intermediate yield wheat producing areas where the greatest potential for increased yields exists. By intermediate yield areas is meant principally wheatfields with yields ranging from 300 to 600 jin per mu. Such areas account for 51 percent of the province's total grainfield area, and account for 48.8 percent of the province's total grain output. They are characterized as follows: Production conditions are fairly good, the irrigated area averaging 1.26 mu per capita. They are similar in this way to high yield areas, but soil fertility is poor, and levels of production techniques comparatively low. All that is needed is to focus attention on them, and their potential for increased yields will be very great; results will show quickly; and the grain production situation can be mastered.

Recently we assembled comrades from five representative intermediate yield counties to talk about the issue of wheat care in intermediate yield counties. In these intermediate yield counties, wheat yields fluctuate around an average 2000 jin or so per mu. Wheat yields per unit of area may vary by as much as 100 jin between a bumper year and a meager year; yields are low and inconsistent. The main reasons by these intermediate yield area's output cannot be made to rise very rapidly are, first of all, insufficient soil fertility. A look at survey data from 14 intermediate yield wheat growing counties in which soil surveys have been completed shows a soil organic content of only 0.7 to 1 percent; total nitrogen to be 0.05 to 0.08 percent, and quick acting phosphate to be only between 3.3 and 8.6 parts per million, or a general 5 parts per million. Not only does it lack nitrogen, but it is seriously deficient in phosphate. Second is the amount of fertilization is little. The quantity of coarse organic fertilizer used has not increased for many years. Amount of nitrogenous chemical fertilizer used averages only 50 jin per mu of wheatfields, about 50 jin less than for high yield wheat growing areas. The amount of phosphate fertilizer used is also very little. Representative sampling shows the area of this kind of wheatfield fertilized with phosphate fertilizer amounts to less than 30 percent of the total wheatfield area. Phosphate fertilizer applications average less than 10 jin per mu, and sometimes only 3 to 5 jin per mu. Third is the slapdash care of poor quality manifested in failure to sow seeds, irrigate, apply top dressings of fertilizer, hoe and rake, or eradicate insects on time. For these reasons, the intermediate wheatfield area produces little tillering, and a reduced number of mature heads, the number of heads averaging about 200,000 per mu, which is from 100,000 to 200,000 fewer heads than from high yield wheatfields.

In order to come to grips with wheatfield care in intermediate fields, in light of the existing major technical problems existing at the present time, emphasis should go to the following key measures.

First is equitable distribution of chemical fertilizer, emphasis going to the fertilization of intermediate yield wheatfields. According to fertilizer experiments conducted by the Provincial Agriculture Crop Institute on wheatfields with different levels of yields, when 1 jin of chemical fertilizer per mu was applied to fields with yields of less than 300 jin per mu, yields increased by 3.7 jin. For wheatfields with yields of between 300 and 600 jin per mu, 1 jin of chemical fertilizer increased wheat yields by 2.3 jin. For wheatfields bearing yields of more than 600 jin, 1 jin of chemical fertilizer meant an increase in yields of only 0.3 jin per mu. Similarly, 1 jin of chemical fertilizer used on an intermediate yield wheatfield can bring a wheat yield of 2 jin more than if used on high yield wheatfields. If 15 more jin per mu of chemical fertilizer could be applied to intermediate yields, the province's 20 million mu of intermediate yield wheatfields could produce 600 million jin more of weat. When heavy early fertilization of intermediate yield wheatfields for greening-up was stressed, results were better than from application of fertilizer for jointing.

Next, attention to use of nitrogenous and phosphate fertilizers in proper proportions. The soil in intermediate yield wheat growing areas are seriously phosphate deficient, and results achieved from fertilization with phosphate are extremely remarkable. In places that have not been fertilized with phosphate base fertilizer or seed fertilizer, in particular, attention should be especially given to increased phosphate fertilization, but fertilization with a mixture of nitrogenous and phosphate fertilizer. Now is the time to combine irrigation for greening up with top dressings of phosphate and nitrogenous fertilizer.

Third is full use of existing water sources, making full advantage of increased benefits in production from water conservancy facilities. This year the weather is dry and soil moisture conditions in wheatfields are bad. Much attention must be devoted to irrigation. First should be a general watering for greening up. Effort should be made to make a total of three or four waterings. The former method of heavy watering at the outset and a slackening off at the end should be changed.

Fourth is timely care to assure quality. This requires, first of all, prompt hoeing and raking, hoeing and raking being intensified on wheatfields with a hard, cracked surface to conserve soil moistuer and increase warmth. Following watering, the wheat should be hoed at the right time, and for late growing and feeble wheatfields hoeing and raking is of primary importance to increase temperature and conserve soil moisture for the promotion of root growth. Second is spraying with phosphorous. At the time of flowering, spraying should be done using potassium dihydrogenphosphate to meet need for the element phosphorous during the flowering period. Third is prevention and control of wheat aphids done in combination with the spraying of phosphorus. Fourth is watering the wheat with Huang Shui [7806 3055] to guard against hot, dry winds.

FIGURING AMOUNT OF GOODS OR FUNDS OWED TO COLLECTIVE

Shijiazhuang HEBEI RIBAO in Chinese 10 Mar 82 p 2

[Article: "How To Set Commune Member Payments for Collective Withholdings Following the Contracting of Work Tasks to Individual Households"]

[Text] How to set fixed amounts of products to be paid to the collective by commune members in production teams that have instituted a responsibility system of contracting work tasks to individual households is a major component in the perfection of responsibility systems. The equitability of amounts paid has a bearing on the major matter of whether the relationship among the state, the collective, and individual commune member can be handled correctly. Since specific situations of land, population, outputs, fixed procurement quotas, income, and indebtedness vary from one production team to another, the amount to be paid will also differ, so that is the proper amount to be paid? It has to be set after totaling the balance sheets.

First an equitable amount of collective consumption and collective accumulation has to be set. Following the contracting of work tasks to individual households, collectives must continue centrally to manage and distribute a certain amount of products and funds, using them to assure state requisition procurement and revenues, and to assure collective consumption and accumulation. The items and quantities for collective consumption require the figuring of two different accounts, namely the grain consumption account and the funds consumption account. Grain consumption includes, seeds and grain for livestock feed; grain allowances for cadres, livestock feeding personnel, teachers in civilian operated schools, electrical workers, and barefoot doctors; grain for the care of households enjoying the five guarantees [children and infirm old persons who are guaranteed food, clothing, medical care, housing and burial expenses by the people's communes], dependents of martyrs and servicemen, and hardship households; and grain assistance given those sent elsewhere to work. Funds consumption includes money for grain consumption, production expenses uniformly paid in cash, management expenses, property depreciation expenses. In order to take further advantage of the superiority of the collective economy, following the contracting of work tasks to individual households, a certain amount of accumulation has to be retained. Before contracts are signed, this amount should be set on the basis of policies enacted by superior authorities in combination with the actual circumstances of the production team, the amounts for collective grain consumption, funds consumption, and accululation being decided upon one by one.

Second is calculation of centrally managed allocations of goods and sources of funds, income being balanced against outgo in a preliminary test calculation of the amounts of goods and funds that commune members will be required to pay. Following the contracting of work tasks to individual households, some production team collectives retained a small portion of land held in reserve for emergency use, and scattered plots of unused land, and they retained some economically diversified projects. These were generally contracted to the work force on specialized contracts. In this way, goods allocated under central management of the collective came from payments made by commune members contracting work tasks and from payments from specialized contracting. Funds allocated under central management came from the conversion into money of goods paid by commune members contracting work tasks, from payments out of net earnings from specialized contracting in farming, forestry, animal husbandry, sideline occupations, and fisheries, and from funds allocated by communes and brigades. By balancing income from sources of funds against expenditures of funds for use, it is possible to make a preliminary calculation of the quantity of goods and funds commune members will be required to pay. Some formulas illustrate this point.

Payment of goods (such as grain, cotton, and edible oil) from the contracting of work = state requisition procurement + collective consumption - payments from specialized contracting.

Funds paid from contracting for work = taxes + collective consumption = collective accumulations - net income payments from various specialized contracting.

Third, the products (grain, cotton, and edible oil) that should be paid by commune members converted into money terms are compared with the funds to be paid. Results of such a comparison can show three circumstances. First, payment of funds as the monetary value to payment with goods. This shows that the goods paid by commune members, no matter whether distributions in the form of actual goods or distributions in the form of value can be assured for the state or retained in sufficient amounts for the collective. When the total of the various goods to be paid are divided by the population (or the total land contracted for work), the amount of goods that each person (or each mu of land) should pay the collective is derived. Second, when the monetary value of the various goods paid is less than funds paid. This shows that in paying goods in this way, only distributions in the form of actual goods can be assured the state and sufficient amounts kept for the collective. However, the country has no assurance of distributions in the form of value and the collective will be unable to retain sufficient amounts. Under these circumstances, the funds shortfall will have to be converted to increased quantities of grain, cotton, and edible oil paid, so that the monetary value of goods paid will be equal to funds paid. Third is when the monetary value of various goods paid is greater than funds paid. This shows that when goods are thus paid, distributions in the form of actual goods may be assured the state and sufficient retention guaranteed the collective; moreover, there will be a surplus of distribution in the form of value of the funds paid. Under these circumstances, the quantity of goods paid cannot be reduced; reduced distributions in the form of actual goods cannot be carried out. Surplus funds may be converted into a certain quantity of goods and proportional payments of cash made to individual households.

BRIEFS

SPRING RAINFALL--Most areas of Heilongjiang Province experienced spring rainfall from 1 to 4 May. Longjiang, Gannan, Tailai and Fuyu counties of Nenjiang Prefecture and Qigihar Municipality had heavy rainfall measuring 20 to 57 millimeters. The northern area of Heihe Prefecture and the central area of Nenjiang Prefecture had moderate rainfall measuring 12 to 19 millimeters. The rest of the province had rainfall under 10 millimeters. Drought in the southern area of Nenjiang Prefecture and the southwestern area of Suihua Prefecture has been alleviated. However, drought still exists in Zhaodong, Zhaozhou and Zhaoyuan counties. Waterlogging in the eastern area of Hejiang Prefecture is worsening. [SK060856 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 5 May 82]

PROVINCIAL FLOODS--According to an analysis of past flood cycles, water will still be abundant in the major rivers of Heilongjiang Province this year, and some rivers will possibly bring comparatively greater floods. According to statistical data, there were great floods in the rivers in northern China in the few years after the great floods in the rivers in southern China. For instance, the Chang Jiang had floods in 1930 and 1931 and Songhua Jiang had a flood in 1932. Chang Jiang and Huang He had floods in 1954, and then Songhua Jiang again in 1957. Since there were floods in Chang Jiang and Huang He in 1981, there may be great floods in the province in the following few years. According to the Central Weather Bureau, this year in most areas of the province precipitation will be 10 to 30 percent above normal. In southeastern areas, precipitation will be 20 to 30 percent above normal. In the eastern part of the province, plagued by waterlogging last year and which had rather abundant rainfall this spring, there may be continued and worsen waterlogging to cause disasters if heavy rain falls this year. [SK201007 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 19 May 82]

BEET SUGAR--Harbin, 18 May (XINHUA)--Heilongjiang Province, China's leading beet sugar producer, produced 365,000 tons of beet sugar in the 1981-82 pressing season, recording an alltime high, according to the provincial light industrial department. The figure represents a 15.5 percent increase over the previous season. The department attributed the increase to the policy of encouraging peasants to grow sugar beets and to a rise in the purchase price. Last year, 42 of the province's 64 counties produced 3.36 million tons of sugar beets, the department said. In an effort to expand the sugar refining capacity, the province has completed two new sugar refineries, and transformed and expanded 10 others, thus adding an annual refining capacity of 82,000 tons to the total. CSO: 4020/132

BRIEFS

WHEAT PRODUCTION MEETING--With the approval of the Henan Provincial People's Government, the Provincial Agricultural Committee held a meeting on inspection and assessment of wheat production, which lasted 6 days and concluded in Nanyang on 17 May. Responsible comrades of agricultural departments of all prefectures and municipalities and experts in wheat discussed the summer grain production situation in the province, looked into and arranged for summer farmwork and summed up experiences in wheat production. The meeting demanded that leaders at all levels formulate the programs for next year's wheat production. The meeting also demanded that leadership organs at all levels improve work style, reduce the number of conferences to a minimum and send a large number of cadres to grassroots units to help them solve practical problems in the course of production. [HK251429 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 20 May 82]

ZHOUKOU PREFECTURE COMBATS DROUGHT--Zhoukou Prefecture has taken an active part in combating drought and protecting wheat and spring-sown crops. Since the beginning of April, the drought situation in this prefecture has become more and more serious. Of the 7.2 million mu of wheat throughout the prefecture, 3.5 million mu of wheat has been seriously affected by drought. Because of the drought, the prefecture has been unable to sow some of its late fall harvested crops. To ensure the normal growth of wheat and spring-sown crops, the prefectural CCP Committee and the administrative commissioner's office promptly held various conferences, demanding that the cadres and the masses throughout the prefecture take effective measures and go all-out to combat drought. Relevant departments must vigorously support them materially and technologically to combat drought. At present, the prefecture is using 11,000 diesel engines, 4,500 motors, 1,900 irrigation sprinklers and 350,000 small agricultural machines and tools to combat drought. Fugou County has irrigated 290,000 mu of wheat. By 4 May, the prefecture had sown late fall harvested crops over 2.15 million mu and irrigated wheat over 1.1 million mu. CSO: 4007/422

BRIEFS

PIG OUTPUT--Wuhan, 19 May (XINHUA)--Hubei Province had 13.61 million pigs by the end of March, an increase of 600,000 over the same period last year. The number of pigs in the province began a downward trend last year because of lack of fodder following the serious flood disaster in 1980. In view of this, the province took a number of effective measures to promote pig production, including distributing land to production teams for growing fodder. These measures are instrumental to the rise of pig production. [Beijing XINHUA Domestic Service in Chinese 0044 GMT 19 May 82]

PIG PROCUREMENT--At the Hubei provincial conference on pig production on the afternoon of 24 May, Huang Zhizhen, provincial CCP Committee secretary and vice governor, talked on the procurement of pigs, stressing that it is now the busy season for commune members to sell pigs to the state and relevant departments must not stop procuring pigs or limit the number of pigs procured. Relevant departments must also not temporarily leave behind, in the houses of commune members, the pigs which have been procured. Thus, we can protect commune members' enthusiasm for selling pigs to the state. The number of pigs raised and procured this year is more than that last year. [Wuhan Hubei Provincial Service in Mandarin 1100 GMT 25 May 82]

CSO: 4007/422

BRIEFS

RAPESEED HARVEST--A bumper rapeseed harvest has been reported from Yueyang Municipality, Hunan Province. The 105,000 mu of rape in the municipality produced 187,000 dan of rapeseeds, a 70 percent increase over the 1981 output. [OW061243 Changsha Hunan Provincial Service in Mandarin 1100 GMT 31 May 82]

BARLEY PRODUCTION--Changsha County, Hunan Province, harvested 873,000 jin of barley from 3,800 mu last winter. [Changsha Hunan Provincial Service in Mandarin 1100 GMT 31 May 82]

COMMUNE, BRIGADE ENTERPRISES--After the readjustment, rectification and improvement of their management, commune and brigade enterprises in Hunan Province have tapped potential and carried out technical innovation and modification. As a result, they have greatly improved their economic returns. Last year, the labor force of commune and brigade enterprises throughout the province accounted for 7 percent of the total labor force of the rural areas and the income derived from their output accounted for 29 percent of the total income of the rural areas and was some 57 million yuan more than in 1980. Each 100 yuan of fixed assets of commune-run industrial enterprises made a profit of 11.5 yuan and each 100 yuan of circulating funds made a profit of 49.5 yuan. [Changsha Hunan Provincial Service in Mandarin 2310 GMT 8 May 82]

WEATHER REPORTING SERVICE ESTABLISHED FOR SPRING PLANTING PERIOD

Beijing RENMIN RIBAO in Chinese 18 Mar 82 p 2

[Article: "Jiangxi Provincial Meteorology Bureau Begins Meteorological Service for Spring Sowing. Helps Peasants Promptly Understand Weather Changes"]

[Text] Recently the Jiangxi Provincial Meteorology Bureau held a symposium on meteorological service for spring sowing attended by meteorology station chiefs and professional personnel and research personnel concerned from the province, prefectures, and municipalities. The symposium took up the subject of how to do a good job of meteorological service during spring sowing this year, making a comprehensive study of and working out actions to be taken on weather, climate, and agricultural meteorology.

Provincial, prefectural, municipal, and county meteorology bureaus set up spring sowing meteorology service teams headed by a bureau leader and staffed by technical mainstay cadres for forecasting, agricultural meteorology, and climate. The Provincial Meteorological Bureau required each meteorology station and post to statisticalize the frequency of disastrous weather, its route, its intensity, and the extent of damage done during the spring season (March-May) over the years in their local prefecture and county, the work to be completed before mid-March. This information was to be plotted on maps and charts for display outside forecast offices so that every forecaster would have a mental conception. When disastrous weather is in the offing, all posts and stations are to give strict attention to weather changes, set up 24-hour watch teams, and promptly organize technical mainstay cadres to hold consultations on the weather to make sure that no failures occur in reporting. The county bureau is to allocate a certain force to go into the frontlines of production to set up service liaison points in areas having different kinds of crops.

Jiangxi Province has established a meteorological service and intelligence network in three fields. One is a disastrous weather watch network in which the provincial meteorological stations and posts all participate. The second is a representative agricultural meteorology intelligence network set up by 20 county meteorology bureaus. Third is the radar monitoring network that includes weather radar installations at Nanchang, Jinggangshan, and Zhangzhou.

Right now the Jiangxi provincial meteorological system is in process of giving widespread publicity to spring sowing meteorology. They use publicity media such as newspapers, broadcasts, and television, and they publish various kinds of small meteorology papers. They have set up meteorology publicity signboards in country fair markets, making all possible efforts to transmit to the broad peasant masses spring sowing weather forecasts and agricultural meteorology intelligence so that they can promptly understand weather changes and use the science of meteorology to plan, plant, and care for their responsibility fields.

BRIEFS

GANZHOU PREFECTURE RAPESEED--Ganzhou Prefecture, Jiangxi Province, has reaped a bumper harvest of rapeseed with total output exceeding 221,000 dan, or 63.6 percent more than in 1981. Harvesting of rapeseed in Jiangxi's Shangrao Prefecture is near completion. It is estimated that the prefecture's total rapeseed output will reach 583,577 dan, or an increase of 13.73 percent over 1981. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 25 May 82]

FIELD CROP SOWING COMPLETED

SK160847 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 15 May 82

[Text] According to our contributing reporter (Zhou Jinqiang), the sowing of field crops has been basically completed throughout the province. According to statistics compiled on 13 May, 88.2 percent of the planned acreage for field crops were sown. The sowing of field crops has been finished in all areas except for a few places in the western and southern parts of the province where the sowing is not yet finished due to serious drought.

This year, the sowing of field crops has taken place under a serious drought. In the face of the drought, the broad masses of commune members and cadres in various localities [sentence indistinct] have tried in every possible way to combat drought. Chaoyang Prefecture made the best use of soil moisture to sow field crops. [Sentence indistinct] When the drought was alleviated somewhat as a result of two propitious rainfalls, commune members went all out to set off an upsurge in spring sowing and thus accelerated the tempo of that work.

While mapping out farming plans, all localities paid attention to readjusting the grain-growing acreage and properly arranged the acreage sown to cash crops and maize under the prerequisite of stabilizing the grain areas. Compared with the corresponding 1981 period, maize-growing acreage in the province decreased some 2 million mu and sorghum growing acreage increased 1.17 million mu. In Jinzhou, Yingkou and Liaoyang municipalities and in Chaoyang Prefecture, some 697,000 mu of cotton were sown, exceeding the plan by 16.3 percent.

The province has also made progress in scientific farming this year. The vinyl-covered areas for growing peanuts, cotton, tobacco and vegetables totalled 292,000 mu, 4.3 times that of 1981. This year, Fushun Municiplaity has made arrangements for eight scientific experimental items for growing paddy rice, soybean, millet and peanuts. The acreage sown to [words indistinct] of soybean on experimental basis is over 200,000 mu, accounting for 70 percent of all soybean fields.

The transplanting of rice seedlings is in full swing in the province. According to statistics, Shenyang and Yingkou municiplaities and Donggou and Fushun counties transplanted some 300,000 mu of rice seedlings as of 13 May.

CSO: 4007/422

BRIEFS

INSECT PESTS--Since late April, insect pests have been reported in farmlands and orchards. This has aroused the attention of departments concerned. Steps have been taken to eliminate them. A certain moth spread over 1.1 million mu of mountainous area in Liaoyang County. Scarabs have been discovered in some communes in Jin County. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 17 May 82]

PROVINCE PROFITS FROM AFFORESTATION--The Liaoning Provincial CCP Committee and the people's government convened a forum on developing the province's eastern mountainous areas 7-12 May in Fushun. Forum participants contended that great progress has been achieved in the implementation of the policy of comprehensive development with stress on forestry in the eastern mountainous areas. Practice has shown the correctness of this policy. In the future, we must persistently implement it. During the past 3 years, about 1 million mu of trees were planted in the eastern mountainous areas. Consequently, water and soil have been better conserved. Grain output has stabilized at 2 billion jin or more. Grain rations of commune members have increased to 489 jin from 435 jin. As the collective economy has increased continuously the per capita income has increased from 91 yuan to 116 yuan. [SK201012 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 18 May 82]

COUNTY SEEDLING GROWING--Liaoning Province's Changtu County was stricken by drought and low temperatures in the late stage of spring sowing and plowing this year. According to an investigation made by the county agriculture department, seedlings on 200,000 mu of cornfields are poorly developed and are third grade seedlings. If we fail to adopt remedial measures, the county may suffer a reduction of grain output by 110 million jin. To counter this, the county CCP Committee and the people's government invited agronomists and agricultural technicians to discuss ways to promote and accelerate the growing of third grade seedlings. Now some 170,000 laborers are joining this task. Some 39 million mu of field crops have been replanted, 280,000 mu have been banked and 360,000 mu have been leveled. [SK242210 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 23 May 82]

COTTON PRODUCTION--Chaoyang Prefecture in Liaoning Province had cultivated 272,000 mu of cotton by 15 May, overfulfilling the state plan by 43.3 percent. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 19 May 82]

PROVINCIAL RAINFALL--Being without any heavy rainfall in the past 30 months, Chaoyang Prefecture, Liaoning Province, had two heavy rainfalls on 27 April and on 2 to 4 May. Spring sowing is in full swing as soil moisture is sufficient. Over 400,000 mu of farmlands are sown in the prefecture every day. [SK070514 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 6 May 82] Rain fell in most of Liaoning Province from the night of 18 May. As of 1400 on 19 May, Kuandian County had 37 millimeters of rain. Precipitation in Tianling Prefecture, most of the Dandong area and the eastern part of Benxi area ranged from 11 to 18 millimeters. Other areas had rainfall totalling 4-10 millimeters. The Dalian area and most of Jinzhou had only 1-3 millimeters. This rain is beneficial to the seedling emergence of field crops and the growth of vegetables. However, due to scanty rainfall, drought in the southern part of the province remains serious. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 19 May 82]

CSO: 4007/422

BRIEFS

CASH CROP--Ulanquab League in Nei Monggol region has expanded its seasame sowing acreage to 1.71 million mu in 1982, an increase of 400,000 mu over the previous year. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 23 May 82]

SHEEP BREED--A new breed of sheep, developed by livestock scientists in Nei Monggol after 30 years of efforts, has passed an acceptance test by a relevant state department and was designated by the regional people's government as Aohan thin-hair sheep. Now the region has 300,000 head of such. Last year the region sold 7 million jin of wool of these sheep to the state. [SK262233 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 25 May 82]

RURAL CONSUMPTION--Supply and marketing departments have organized great qualities of manufactured goods to rural areas. During the first 4 months, they supplied means of agricultural and livestock production worth 78 million yuan and daily necessities worth 390 million yuan. These are increases of 16.9 and 7.5 percent respectively over the corresponding 1981 period. Peasants and herdsmen in rural areas have shown unprecedented enthusiasm in purchasing means of production. By the end of April, 256,100 tons of chemical fertilizer had been sold in the region, up 19.9 percent over the corresponding 1981 period. Some 3.68 million small farm implements had been sold, an increase of 34.1 percent over the corresponding 1981 period. [SK220901 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 21 May 82]

REGION HELPS BACKWARD AREAS--The Nei Monggol Regional People's Government decided to allocate 30 million yuan from the state funds which were appropriated to the region for developing economically backward areas in 1982 to help old revolutionary bases, mountainous areas, remote areas, pastoral areas and backward areas develop production. This fund will be used this year to establish 10 rejuvenating forest areas, six banners, counties and communes that can ensure a comprehensive development of agriculture, animal husbandry and forestry and four collectively-owned mechanized agricultural and livestock farms and to help minority people raise animals. Hohhot Municipality and Ih Ju, Ju Ud, Bayannur and Alxa leagues have also donated 4 million yuan to support this work. [SK242212 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 23 May 82]

MARKETABLE GRAIN BASE--Ju Ud League in Nei Monggol region has decided to build a 4-million-mu key marketable grain base managed by 600 brigades in (Chengchuan) District. It is expected to raise the per-mu yield from 300 jin to 400 jin to achieve a grain output of 1.6 billion jin in 1985, which will be 66 percent of the league's total. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 23 May 82]

ARTIFICIAL RAIN--In support of Nei Monggol's drought combat work, the State Council and the Military Commission of the CCP Central Committee on 11 May dispatched planes to make artificial rain in areas between Qilian County in Qinghai and Togtoh County in Nei Monggol. The artificial rain is conducive to the agriculture of Nei Monggol's Tomochuan areas. [SK201010 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 18 May 82]

COLD SPELL--Nei Monggol Regional Meteorological Observatory released a forecast of strong winds and cold weather at 1700 on 14 May. A cold spell will move into the region on the early morning of 15 May. Most areas in the central and eastern parts of the region will be hit by 7 to 8-class strong winds and will experience a slight or medium amount of rain and snowfall. From the afternoon of 15 May to 17 May, temperatures will drop 8 degrees. Other areas in our region will be hit by a 6-class wind. [SK172202 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 14 May 82]

REGIONAL RAINFALL--On 11 May, light to moderate rains fell in central and western areas and heavy rains fell in a few areas of Nei Monggol region. Even the southern area of Alaxa League and western Ih Ju League, which had very little rains last year, had 7 to 18 millimeters of precipitation on 11 May. Hulun Buir, Xingan, Jirem, Ju Ud, Xilin Gol and Ulanqab leagues and Hohhot, Baotou and Wuhai municipalities have enough soil moisture. Drought in other areas of the region has also been relieved. [SK131308 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 12 May 82]

BRIEFS

PROVINCIAL RAINFALL--According to a report by the Shaanxi Provincial Meteorological Bureau, on 26 and 27 April it rained in Shaanxi Province and the rainfall in the larger part of this province varied from 10 to 15 mm. The rainfall in Suide, Qingjian, Yanchang, Luochuan, Fugu and Yanchuan counties in north Shaanxi, Xian Municipality and Gaoling, Lantian and Fengxiang counties in Guangzhong and Hanzhong and Hanyin counties in south Shaanxi was 16 to 20 mm. The fainfall in Zhidan, Changwu, Baoji, Lintong, Weinan, Hua Yang and Xixiang counties was 21 to 40 mm. This rainfall has alleviated the drought situation in some places in north Shaanxi and Guangzhong and is beneficial to spring sowing and to the growth of summer crops. TANFANG PREFECTURE PROMOTES FARM MACHINERY MANAGEMENT RESPONSIBILITY SYSTEM

Jinan DAZHONG RIBAO in Chinese 10 Feb 82 p 2

[Article by Li Shanquan [2621 1472 3123]: "Tanfang Prefecture Implements the Farm Machinery Management Responsibility System--Farm Machinery Managed Well and the Economic Gain Is High"]

[Text] Tanfang Prefecture has actively implemented the farm machinery management responsibility system and has realized visible economic results.

In recent years, the number of farm machinery units has continued to increase in Tanfang Prefecture. At present, the whole prefecture already owns 33,091 tractors, and the total power of farm machinery has reached 380,000 horsepower. The total value of fixed assets in farm machinery has reached over 500 million yuan, constituting over one-third of the fixed agricultural assets of the whole prefecture. To further manage and use these units of farm machinery well, the committee of Tanfang Prefecture and the administrative office studied and decided to further strengthen and perfect the farm machinery management responsibility system, improving the percentage of farm machinery in good condition and the rate of utilization so that the machinery can fully develop its function in production. To implement the farm machinery management responsibility system, they held farm machinery management cadre training classes at each level to train a backbone force in farm machinery management. Later, each county and city implemented different forms of the farm machinery management responsibility system by suiting measures to local circumstances according to the actual situation of the locality. According to statistics, among the 237 commune tractor stations throughout the prefecture, 50 stations have implemented contracting tractors to professionals and sharing a percentage of the profits, constituting 24 percent. There are 138 stations that have implemented accounting for each tractor and the five quotas and one reward system, constituting 58 percent. There are 12 stations that have implemented the system of floating wages with rewards, constituting 5 percent. There are 15 stations that have implemented conprehensive contracts, constituting 6.5 percent. There are 15 stations that have implemented quota management, constituting 6.5 percent. There are 10,104 units of production teams and brigades throughout the prefecture that have farm machinery. Among them, 21 percent have implemented contracts to specialists and linking remuneration with production, and 42 percent have implemented unified management and accounting for single machinery units, 9 percent have implemented the system of comprehensive contracts with several unified categories, and 28 percent have implemented fixed quota management.

The implementation of the farm machinery management responsibility system has unified authority, responsibility and profits, and cadres and commune members have strengthened self-awareness in managing and using farm machinery well. For example, the Dawangzhuang farm machinery team of Chengguan Commune, Gaomi County, implemented contracts to specialists. The percentage of farm machinery in good condition reached above 90 percent. Mechanized farming reached over 80 percent. In the past, this brigade suffered losses of over 10,000 yuan in farm machinery each year. Last year, the farm machinery team submitted over 30,000 yuan in profits to the brigade and kept 16,500 yuan. Each farm machinery operator received a reward of 359 yuan. As the level of agricultural mechanization rose, this brigade freed 76 percent of the labor force to engage in industrial and sideline production and the economic revenue of the collective continued to increase.

BRIEFS

COTTON APHID PEST--According to information released by the Shandong provincial crop disease and the insect pest investigation station, the current dry and hot weather is good for growth and reproduction of cotton aphides. The aphid density is rising quickly. In some areas, about 30 to 50 percent of cotton crops are hit by aphides, and there are over 500 aphides in each 100 cotton plauts. [SK252210 Jinan Shandong Provincial Service in Mandarin 2300 GMT 24 May 82]

CASH CROP PLOTS--Jining Prefecture, in Shandong Province, has strived to improve economic returns in developing a diversified economy by vigorously attending to cash crop plots. The prefecture's income from the diversified economy totaled 360 million yuan for the first 4 months of this year, up 39 percent over the corresponding 1981 period. Avoiding cutting into good farmland, communes and brigades in the prefecture have expanded cash crop plots to 580,000 mu from last year's 320,000 mu. [SK172206 Jinan Shandong Provincial Service in Mandarin 2300 GMT 14 May 82]

WINDS THREATEN WHEAT GROWTH--Since May, wheatfields in Shandong Province have been repeatedly hit by hot and dry winds. Over 40 million mu have been affected. Hot and dry winds came earlier this year, were stronger and wrought more havoc than last year. Except for Jining Prefecture, the southern part of Weifang Prefecture and the middle part of Linyi Prefecture, most wheatfields in the province have been hit by winds. [SK262223 Jinan Shandong Provincial Service in Mandarin 2300 GMT 25 May 82]

LIAOCHENG PREFECTURAL AGRICULTURE--Jinan, 26 May (XINHUA)--Liaocheng Prefecture, Shandong, is growing 4 million mu of cotton. It produced 3.66 million dan of cotton in 1981. It also grows 3 million mu of wheat. [OW300843 Beijing XINHUA Domestic Service in Chinese 0155 GMT 26 May 82]

PROVINCE TAKES MEASURES TO RECOVER FROM WINDSTORM

HK200310 Taiyuan SHANXI RIBAO in Chinese 9 May 82 p 1

[Report: "The Provincial Agricultural Department Demands That the Province Urgently Mobilize to Overcome the Windstorm Disaster and Strive for a Bumper Harvest"]

[Text] Editor's note: In early May, our province was hit by a low-temperature windstorm from the north to the south and the production of wheat, cotton and vegetables was damaged. We must neither despair nor slacken our vigilance in the face of this natural disaster. Leading members at various levels must go to the frontline, urgently mobilize the masses, the effective measures, combat the disaster and provide disaster relief, and strive to repair the damage caused by the disaster. All departments and trades must also take action, actively allocate and transport materials and support the peasants in combating the disaster and striving for a bumper harvest. [End editor's note]

Beginning during the night of 1 May to 3 May, a windstorm and falling temperatures struck our province. In most places, wind reached force 59 to force 8 (on the Beaufort scale) and in some places, it reached as high as force 11 and force 12. Such a windstorm had never been seen before in our province. The production of wheat, cotton and vegetables was damaged. To combat natural calamities and strive for a bumper harvest, the provincial agricultural department has put forth three concrete measures a few days ago.

This windstorm has adversely affected the growth of wheat. At present, wheat in the southern part of Shanxi is in the initial period of flowering and filling. Due to the intensity of the windstorm and the loss of water content, the pollination is low and the boot leaves of the wheat suffer from root lesions. A small amount of the wheat, which had been too closely sowed, is suffering from lodging. According to the statistics of Yuncheng Prefecture, some 411,000 mu of wheatfields in the whole prefecture have obviously been affected by the disaster. The seedling cotton has also been damaged by this windstorm. According to incomplete statistics from Hongkong Yicheng, Xiangfen, Fushan and Ji Xian counties and Houma Municipality in Linfen Prefecture, about 30,000 mu of cotton plants had their seed leaves tore off. This year, the area of cotton plants protected by plastic sheets has increased throughout the province. In the portion of cottonfields where the plastic sheets had not been properly secured, cotton seedlings were damaged as a result of the plastic sheets being tossed by the wind. In Yuncheng Prefecture, some 6,000 mu of cottonfields had their plastic sheets ripped or blown away. The cotton seedlings lost their seed leaves as a result and they have ceased growing.

This windstorm also damaged vegetable production in urban suburbs. According to preliminary statistics from Qingxu County and the northern and southern suburbs of Taiyuan Municipality, more than 8,000 mu of vegetables have been affected. Of the 839 plastic covered sheds in the whole municipality, about 550 were damaged or destroyed. Of the 30,000 hothouses and more than 3,000 mu of plastic sheet covered vegetable fields in the municipality, about a third had their plastic sheets lifted or their hothouse installations destroyed. Five of the communes in the suburbs of Changzhi Municipality have been more seriously hit by the disaster. Of the 200 large-size plastic covered sheds in Datong Municipality, some 10 have been destroyed.

In view of the above-mentioned conditions, the provincial agricultural department has called on various localities to strengthen leadership over disaster relief work, adopt corresponding remedial measures according to the extent of crop damage as a result of the disaster, and reduce the damage caused by the disaster to a minimum.

1. As for wheat, they must strengthen irrigation and spraying of phosphatic fertilizer. On the one hand, they must restore the vitality of the wheat affected by the disaster as quickly as possible; on the other hand, they must take precautionary measures against high temperatures and try to increase the kernel weight of the wheat by means of adding water and fertilizer in suitable amounts.

2. As for cotton, they must continue to grasp firmly and properly the work of examining cotton seedlings and carrying out replanting. They must quickly mobilize the masses to adopt such methods as cultivating seedlings at the edge of fields, cultivating seedlings in breeding bowls, carrying water for replanting, and carrying out field cultivation transplanting to ensure that the cottonfields will be fully and adequately planted and the seedlings will grow healthy. At the same time, they must conscientiously inspect plastic sheets used to protect the cottonfields and promptly repair and reuse them. Places with suitable conditions should promptly carry out preparatory work for the resowing of cotton and strive to resow a bit more cotton.

3. As for vegetable production, they must mobilize the vegetable farmers to take corresponding measures in the light of different installations, different seedling conditions and different disaster conditions, actively repair the sheds, mend the holes and strengthen the large-size sheds and hothouses. They must repair and rebuild the medium and small-size sheds and hothouses, set up racks and carry out irrigation at the proper time in accordance with the characteristics of different varieties of vegetables and carry out the transplanting and replanting of vegetable seedlings affected by the disaster so that vegetable production can be restored to normal as quickly as possible.

BRIEFS

COMMUNES' DISTRIBUTION WORK--Rural people's communes in Sichuan Province have completed the work of distribution of earnings for 1981. According to the statistics of the provincial agricultural department, despite serious floods in 1981, there was an increase in grain output, investment results and commune members' grain rations. The province's total grain output in 1981 was 620 million jin more than in 1980, and the total earnings of the collectives and the earnings distributed reached 11 billion yuan in 1981. Total expenditures of the province decreased from 3.9 billion yuan in 1980 to 3.6 billion yuan in 1981, and each person in the province saved an average of 3 yuan on each expenditure. THREE-WAY COMPLEXES LEAD TO HIGHER OUTPUT

Kunmin YUNNAN RIBAO in Chinese 9 Feb 82 p 2

[Article by Li Shuliang [2621 2885 2733] et al: "Agriculture-Industry-Commerce Integrated Complexes Under Our Province's Agriculture and Land Reclamation System Are Being Run Better and Better"]

[Text] In the 2 years since the five agriculture-industry-commerce integrated complex companies were set up under our province's agriculture and land reclamation system, they have been run better and better with notable results, fully reflecting the superiority of a coordinated process in agriculture, industry, and commerce.

Specifically there have been some changes, as below:

According to statistics of the general company for the agriculture-industry-commerce integrated complex, last year the five integrated complex companies--Longchuan, Suili, Liming, Chuncheng, and Miqin Dongfeng--rapidly improved their economic results, increasing their total output value by 13.14 million yuan, or 26 percent, over that of some previous years; in 1979, before these five enterprises formed companies, they lost a total of 5.8 million yuan, but last year the companies made a total profit of 6.56 million yuan, or a 166 percent increase over the total profit in 1980.

The tapping of many kinds of managerial sources has changed the past state of affairs created by single-management forms in which "the state was depended on for spending money, the locality for staple food, and the market for non-staple food." Last year the five companies provided the state and markets in various places with over 100 kinds of agricultural and subsidiary products, among which were over 13,700 tons of white sugar, over 600 tons of pork, over 2.5 million jin of milk, 459 tons of powdered milk and malt-milk extract, as well as a great amount of white spirits, wine, candy, sweet cakes, cold drinks, prepared food, vegetables, flowers and plants, fruit, furniture, hardware, and farm tools.

While the province increased its production of commodities, it also expanded the channels for circulation of commodities. The provincial office has signed purchasing and selling contracts with about a dozen provinces, municipalities, and autonomous regions, and within the province the five companies have 167 new commercial network outlets; last year their sales totaled over 20 million yuan, double that of the year before last.

Enlivening country fair trade has promoted price stability. In the past, staff and workers on farms mainly depended on the market for the supply of meat and vegetables, and because there was a great deal of buying on the market the prices of nonstaple foods there were higher than in the city. Now the farms are continuously developing pig raising and the staff and workers are nore than self-sufficient in meat. With plenty of food on the market, the county fairs have been enlivened and price stability promoted, and in particular the prices of meat and vegetables have been stable and in some cases have fallen. Last year the Ruili and Longchuan integrated complex put over 200,000 jin of pork on the market, and the price per jin was about 1 yuan 1 jiao. The vegetables put on the market by Dongfeng Farm account for about half of the total amount on the local market.

The prosperous border area economy promotes the construction of small cities. The three agriculture-industry-commerce integrated companies of Longchuan, Liming, and Dongfeng are located far from the county seat. Around the companies small cities have now been built, with residential areas for staff and workers with lower and middle schools, stores, hospitals, motion picture theaters, bookstores, restaurants, cold drink shops, barber shops, tailor shops, repair shops, depots, and hostels.

PREVENTION OF SPREAD OF MAJOR POISONOUS WEEDS NOTED

Kunming YUNNAN RIBAO in Chinese 31 Jan 82 p 2

[Article by Ye Long [5509 7893]: "Beware of the Spread of Eupatorium Japonicum and Eupatorium Odoratum--Our Province's Plant Protection Experts Point Out that These Two Harmful Weeds Must Be Eliminated"]

[Text] The harmful weeds that seriously threaten the development of livestock, forestry and agriculture--eupatorium japonicum and eupatorium odoratum--have already begun to spread in our province. We should be more alert. This is the call made by plant protection experts and scientific and technical workers who joined the Weeds Research Committee recently founded by the Provincial Plant Protection Society in Kunming.

They pointed out that there are many harmful weeds that endanger our province's livestock, forestry and agriculture, especially eupatorium japonicum and eupatorium odoratum, which pose the most serious threat. These two harmful weeds have a broad adaptability, and they grow and spread very quickly. As soon as they are introduced, they grow to 20 to 40 centimeters during the first year and in the second year they grow to over 80 centimeters. These two harmful weeds have already spread gradually from Simao, Linchang and Baoshan prefectures to Chuxiong, Honghe, Wenshan and Kunming areas. The area damaged by the weeds in Simao and Linchang prefectures alone has reached over 1 million mu. These two harmful weeds affect the growth of grazing grasses in the mountains, young forests and agricultural crops. The damage they cause is described as follows: 1. After these two harmful weeds propagate, grow and spread, they stifle the growth of grazing grasses, young forests and agricultural crops; 2. Livestock that consumes these grasses will suffer from dysentery and asthma and even die. The pollen will also cause rotting of the eyes and nose, and cause pus. A horse at the horse barn in Zhenkang County mistakenly consumed eupatorium japonicum and almost all the horses in the horse barn died. Now these two harmful weeds are spreading continuously. This is very detrimental to the development of livestock production, forestry and agriculture.

How can these two harmful weeds be exterminated? Plant protection experts and scientific and technical workers believe the ideal method is to develop competitive grazing grasses and economic forests to replace these two harmful weeds. Such research and experiments have been conducted by experts and scientific and technical workers. At present, each locality should pay attention. Whenever these two weeds are discovered, the masses should immediately be organized to eliminate them. Localities already suffering damage by the weeds can use picloram, glyphosate, 2, 4-D weeders to eradicate them. In addition, the area of cultivated land must be fixed to prevent land from going to waste and grazing grasses from going to waste.

YUXI PREFECTURE TAKES STEPS FOR BETTER TOBACCO PRODUCTION

Kunmin YUNNAN RIBAO in Chinese 30 Jan 82 p 1

[Article by Shu Quan [2885 0356] et al: "Yuxi Prefecture Draws Up Plans for This Year's Flue-Cured Tobacco Production Early"]

[Text] At the beginning of the new year, the administrative office of Yuxi Prefecture conscientiously analyzed the situation of this year's production of flue-cured tobacco with the determination to even better display the superiority of Yun tobacco, to vigorously tackle the key problem of quality, and to further improve the capacity for market competition, and to improve economic results.

The Yun tobacco of Yuxi Prefecture is well known throughout the country, is the main ingredient for top-grade cigarettes in Beijing, Shanghai, and other places, and is exported to West Germany and other countries. In recent years, the quality, output, per unit area yield, and income of the flue-cured tobacco here have in consecutive years reached the best levels in history. Last year, the prefecture's total output and the purchased amount of flue-cured tobacco both increased by more than 60 percent over those of the previous year, the income of the collective and the commune members more than doubled, and for the first time the proportion of top- and high-grade tobacco broke through the 70-percent mark.

In view of this success, the administrative office of the prefecture analyzed the nationwide trends in flue-cured tobacco development, and concluded that under the new conditions in which the output of flue-cured tobacco is rapidly increasing throughout the country, and in which the amoung of high- and medium-grade leaf tobacco and cigarettes required by domestic and foreign markets has grown, only by improving the quality of flue-cured tobacco and seeking high output with top quality can the prefecture's competitive capacity be strengthened and new markets be opened up. Therefore, the party committee and the administrative office of Yuxi Prefecture are helping all of the counties in the prefecture to vigorously tackle the key problem of the quality of their flue-cured tobacco, and plans this year to raise the proportion of high- and medium-grade tobacco to over 75 percent, thereby obtaining even better economic results than last year.

In order to insure a high output of top quality flue-cured tobacco this year, work has already started on the following items: (1) The prefecture held a top quality-high output experience exchange meeting, which analyzed the potential for top quality and high output of flue-cured tobacco, exchanged and introduced experiences in this respect; and also issued silk banners and certificates of merit to advanced units and commune members for top quality and high output of flue-cured tobacco, encouraging them to further improve the quality of flue-cured tobacco and spur on others. (2) To help the production teams perfect the scientific and technical responsibility system, the prefecture has listed quality improvement as the principal part of contracts. (3) The prefecture is accelerating the training of the flue-cured tobacco cultivation technical force to spread knowledge of scientific tobacco planting. People attending the county- and commune-run flue-cured tobacco training class have completed the course, and these people have already gone to the communes and production teams to explain to the commune members the science and technology of flue-cured tobacco. (4) The prefecture increased the building of curing sheds. The counties have decided to build over 6,800 curing sheds, of which construction has already begun on over 2,300. (5) The prefecture got a good grip on the work of cultivating strong sprouts and of scientifically applying fertilizer. A batch of production teams in Yuxi and Jiangchuan counties arranged tobacco seedbeds well ahead of time, and began to work hard to change the fertilizer structure. (6) The prefecture organized various departments concerned to do well ahead of time the work of supplying materials, funds, and technology for flue-cured tobacco production.

SIX COUNTIES TRY OUT S&T RESPONSIBILITY SYSTEM

Kunmin YUNNAN RIBAO in Chinese 10 Feb 82 p 1

[Article by Wu Ronghua [2976 2837 5478] et al: "Great Achievements Made by Science and Technology Combined Output Responsibility System"]

[Text] The agricultural departments, the scientific and technological departments, and the scientific and technological teams of some communes and production brigades of six counties--Yuxi, Tonghai, Eashan, Yimen, Jiangchuan, and Yuanjiang--have tried out the scientific and technological combined output responsibility system, adopting and signing contractual forms to spread agricultural science and technology. In this, they have achieved marked results. Last year all 33 of the contracts signed for the scientific and technological combined output of spring-sown crops resulted in increased output and harvests, and all commitments for awards and compensation were honored.

After various forms of the agricultural production responsibility system were established in rural communes and brigades in various counties of Yuxi Prefecture, the prefecture successively requested the agroscience departments to help the peasants solve some difficulties encountered in production in order to strive for superior quality and high output in grain and economic crops. In March 1981, the Yuxi Prefectural Science Committee organized prefectural and county agricultural departments, scientific and technological departments, and the agroscience stations of some communes to sign 33 scientific and technological combined output contracts, covering a total area of 13,986 mu, with 1 production brigade, 33 production teams, and 2 peasant households in the above-mentioned 6 counties for raising paddy rice seedlings, changing low-output paddy rice to high-output paddy rice, stabilizing the output of high-output paddy rice, spreading improved varieties of corn, and achieving excellent quality and high output of flue-cured tobacco. The result of the autumn harvest was that increased outputs and increased harvests were achieved contract by contract. For the raising of paddy rice seedlings, 17 jin 3 liang were planted on every mu of land for growing field crops, 14 jin 7 liang less than previously, or a savings of 46 percent; the per unit area yield on the area of 11,708 mu of paddy rice covered by 20 contracts reached 920 jin, an increase over the figure for the year before last of 112 jin 3 liang, or 13.9 percent; on the 158 mu 4 fen of land under flue-cured tobacco contracted for by agroscience institutes in Tonghai, Yuxi, and Yimen counties, good quality and high output were obtained, the average per mu output value increasing by over 40 percent with the highest increasing by over 200 percent; and on the 242 mu 4 fen of land under corn covered by 5 contracts, marked output increases were obtained, with the average per mu output increasing by 40 percent and the highest increasing by 95 percent.

By implementing the agricultural science and technology combined output responsibility system, the prefecture has broken free from the past method of spreading the fruits of science and technology by administrative order, so that authority, responsibility, and benefit have been closely integrated and so that the enthusiasm of the scientific and technical personnel and of the commune members has been aroused quite well. The scientific and technical personnel are conscientious about their responsibilities, and they go to the fields to teach by personal example as well as verbal instruction; the commune members are conscientious about receiving instruction, and they till the land according to instructions from the scientific and technical personnel, which gives joy to the latter and satisfaction to the masses. For the success in the raising of paddy rice seedlings contracted for by the agrotechnical station of Yuanjiang County, the production teams on their own initiative urged the technicians to receive a well deserved bonus, and proceeded to sign contracts for high output of rice and corn.

BRIEFS

PREFECTURE FIGHTS DROUGHT--Yunnan Province's Dali Autonomous Prefecture has organized work teams to promote water storage work among peasants in order to counter potential drought. The leaders of the prefectural CCP Committee and prefectural people's government have led seven work teams to go to counties where the situation of water supply was the worst to inspect and promote building of water conservancy projects. As a result, an adequate amount of wells and channels were dug in order to ensure water supply during dry seasons. [HK251001 Kunming Yunnan Provincial Service in Mandarin 1100 GMT 15 May 82]

TIE YING ON IMPROVING PROVINCE'S FISHERY

HK210921 Beijing RENMIN RIBAO in Chinese 15 May 82 p 2

[Article by Tie Ying, first secretary of Zhejiang Provincial CCP Committee: "Several Questions Concerning the Development of Offshore Fishery"]

[Text] Summary of article: This article expounds on the following five problems related to the development of offshore fishery in Zhejiang Province: First, since Zhejiang is a province with a vast stretch of sea area and rich aquatic resources, offshore fishery is very important in the province's national economy. Second, the policies for the development of offshore fishery should be clearly understood. These policies are to go outward to open up outer offshore fishing grounds, to emancipate people's minds in vigorously developing aquatic breeding in beach and shallow sea areas, and to conscientiously develop the processing and comprehensive exploitation of aquatic products. Third, since there are both sea areas and mountain areas in fishing districts, we should vigorously utilize the favorable conditions provided by both the sea and the mountains and develop diversified undertakings. Fourth, we should implement various forms of the production responsibility system geared to fishery in the light of local conditions and continuously to perfect the system in practice. Fifth, we should strengthen aquatic scientific research, do a good job of investigating the aquatic resources, popularize cultural education and scientific and technical knowledge in the fishing districts and train a new generation of fishermen. [End of summary]

Since the 3d plenary session of the 11th CCP Central Committee, there has been a fine situation in the offshore fishery in Zhejiang Province. This is mainly shown by the following facts: 1) By implementing the policy of readjusting the national economy we have gradually readjusted the structure of our aquatic production, protected our offshore aquatic resources, developed aquatic breeding, and the processing of aquatic products and other diversified undertakings. 2) We have set up and perfected various forms of the production responsibility system geared to fishery which gives play to both the superiority of the collective economy and the initiative in production of individual commune members. Thus we have fulfilled in a relatively satisfactory manner the quotas of purchases and transferences of aquatic products assigned by the state. 3) Along with the development of production and with the changes resulting from the implementation of the policies of raising the purchase prices of aquatic products and allowing negotiable premiums for those goods purchased in excess of the purchase quotas, there have been substantial increases in both the accumulation of the collectives and the income of individual commune members.

The problems we should study are: First, why for more than a decade the annual output of our offshore aquatic production has remained within the range of 14 to 15 million dan and how can we make a breakthrough in increasing production. Second, the problem of the steady decline in the supply of fish for our urban and rural people. In 1981, the average supply of fish per capita at the provincial fixed prices is only 8.9 jin and the quality of the fish supplied is relatively poor. How can we solve the problem of "difficulties in buying fish in an area that was once called the 'land of fish and rice?'" And third, in our fishing areas, 25 percent of the total labor force is redundant. How can we find employment for such a large surplus labor force? The Zhoushan Prefectural CCP Committee has clearly pointed out, "The people want fish to eat and the fishermen want employment. What should we do?" It has called on the cadres at all levels throughout the prefecture to discuss in depth this problem.

Faced with this situation, we are of the opinion that in order to develop offshore aquatic production in our province, we have to further study and solve the following problems:

I. A Full Understanding of the Importance and Role of the Development of Offshore Fishery in Developing Our Province's Economy

There is a vast stretch of ocean area in Zhejiang Province with abundant aquatic resources, which provides great potential to tap in developing economy. This ocean area stretchs from 27 to 31 degrees north latitude, and to the east it extends to the edge of the continental shelf. Its total area is 223,000 kilometers, which is more than twice that of land area of the province. However, we have as yet failed to exploit quite a large part of these aquatic resources to benefit our people. An example of the offshore fishing alone is enough to prove this. Our fishing is chiefly carried out in the fishing grounds along or near the coast. As for the fishing grounds in the outer aquatic areas which lies beyond the 80 meter isobath, we seldom fish there though its area is as large as 98,000 kilometers, which constitute 44 percent of the total aquatic area of the province. Another example is aquatic breeding. We have only utilized 10 percent of the 1.5 million mu of beach and shallow sea area along the province's 2,200 kilometers of coastline that can be utilized for aquatic breeding. Moreover, the output of those areas that we have utilized in aquatic breeding is very low and the total output value of these areas only constitutes 5 percent of total fishery output value of the province. This demands that we widen our field of vision and regard the development of offshore fishery as strategically as important a task in Zhejiang's four modernizations as the construction of the mountainous areas. The decade of fluctuation in aquatic production stems from many causes, but the chief cause is our failure to attach due importance to fishery. Moreover, we overlooked the characteristics of fishery and have adopted quite a large number of measures that were against the natural law of the aquatic areas and that are against the economic law. Today, we should conscientiously sum up our experiences and strive to discover the objective law governing economic development of the aquatic areas. We should also make investigations in order to clearly know our aquatic resources and in order to form correct policies to tap to the full the great potential of the ocean. By so doing we will be able to promote the four modernizations in our province.

II. The Problem on the Policies Related to Aquatic Production

In order to put an end to the fluctuation in offshore fishery we should make new breakthroughs in all the sections of production, including fishing, aquatic breeding and the processing of aquatic products.

1) Open up fishing grounds in the outer offshore areas. This is an inexorable trend of the development of offshore fishery. It also serves to protect the inshore aquatic resources. At present there is such a large number of inshore fishing boats which make the inshore fishing grounds so crowded that it has become imperative for us to restrict their fishing capacity within a certain limit. However, the restriction should be supplemented by giving guidance in opening up new prospects. We should energetically guide the fishermen to develop fishery in the outer offshore areas and regard this as being precisely the important measure for preserving inshore aquatic resources. The problem now is whether we will be able to open up new prospects by going outward and whether there are fish to catch in the outer offshore areas. To solve this problem, we have made a special investigation in Zhoushan. The investigation proves that we have all the favorable factors for going outwards. At present, we have not only a fleet of outer offshore fishing boats with some state-owned fishing vessels as its backbone, but also a number of large motorized sailboats owned by individual fishermen. Moreover, in some counties in Zhoushan and Ningbo prefectures, the fishing communes and brigades that have sound economic bases and high technical standards in fishing are all applying for building bigger new ships with funds raised by themselves in order to meet the demand of extending their fishing operations to outer sea areas. The practice of the Zhoushan No 2 Offshore Fishery Company has proved that there are fish to catch in the outer offshore waters. The 14 old AFS new fishing vessels in that company have caught 12,310 tons of fish during the past 2 years. Seventy-two percent of their fishing operations have been carried out in the outer areas. The average annual output of each of these two fishing vessels is 1,060 tons, of which more than 70 percent have come from the middle and bottom layers of sea waters. They have also caught some fine strains of fish that have never been found in the inshore areas. Other companies have also achieved good results in outer sea fishing. For example, the Zhoushan Fishery Company has achieved relatively good results in catching black scrapers and so has the Ningbo Fishery Company in catching middle and bottom layer fish in the outer offshore areas.

Extending our fishing operations to outer sea areas is the strategic goal in developing our sea fishery. Of course in tactic arrangement we should proceed from reality and strive to make steady progress. As the Zhoushan Islands are relatively near to our outer sea fishing grounds and as the fishermen there have experience in carrying out fishing operations on the sea for a long time, it is feasible to first organize some of the fishing teams of the Zhoushan and Ningbo prefectures to develop outer offshore fishery and at the same time develop fishing vessels and motor sailboats for going further out.

While developing outer sea fishery, we should rationally utilize the offshore aquatic resources under the premise of strengthening the protection of resources. Those species of fish we have fished excessively should now be protected and those that we have failed to fully exploit should now be fully exploited. After years of readjustment the number of motorized sailboats in Wenzhou Prefecture dropped from 794 in 1978 to 712 in 1981, but the total output increased from 580,000 dan to 990,000 dan. In Taizhou Prefecture, because we paid attention to developing drift net and angling operations, we caught 60,000 dan of butterfish, sweetfish and spanish mackerel, which were a 100 percent increase over 1978 and we also caught 120,000 dan of hairtail fish, which were a 70 percent increase over 1978. This proves that in utilizing offshore aquatic resources there is still great potential to tap.

2) We should emancipate our minds and vigorously develop fish breeding in beach and shallow sea areas. Over the past few years, our province has achieved some initial results in developing inshore fish breeding. The area of breeding has continuously been expanded and the varieties become increasingly varified. Ninghai County has taken the advantage of the favorable geographical conditions of Xiangshan Port and Shanmen Gulf and vigorously developed inshore fish breeding. Up to last year, the county utilized 44 percent of the waters that can be used for breeding and the output of its fish breeding constituted 38 percent of its total fishery output. This has proved that there is a bright prospect for aquatic breeding. Of course the natural conditions differ in areas and the capability of aquatic breeding in various areas also differ. However, as long as we attach as much importance to this work as the Ninghai County CCP Committee has done and as long as we adopt corresponding policies that are suited to the local conditions, we will be able to utilize the 1.3 million mu underutilized beach and shallow sea areas and thus substantially raise our income.

Besides the beach and shallow sea areas, we also have a vast area of freshwaters in our coastal counties that can also be used for fish breeding. The total area of lakes and reservoirs is 2.27 million mu in our province. If the area of rivers is added to it, the total area is about 5.53 million mu. This also constitutes an abundant natural resource for developing fishery in our province. In the past few years we have also made some progress in developing freshwater fish breeding. However, there is still great potential to tap in increasing the area of breeding and the output per area. We must vigorously develop freshwater fish breeding in the light of local conditions.

3) We should vigorously develop the processing and comprehensive exploitation of aquatic products. The processing of aquatic products has always been a weak sector in the aquatic production of our province. Year after year we let large quantities of fish and shrimps we have caught become

rotten and inedible. This is really a pity. Now some areas have already begun to develop fish processing. The Ningbo Offshore Fishery Company has developed the processing of black scrapers. It cuts the meat of the fish off and then bakes the meat into dried strips, which sell very well in Japan. The skin and head of these fish are processed into fish powder to be used as fodder. Oil is extracted from the liver of the fish and used as an industrial raw material. In the past 2 years, Wenling Aquatic Product Company has developed the processing and packing of diversified small fish into food, which is well received in the market. Along with the increase in the cold storage capacity of the fishing areas, this work will become increasingly important and we must pay close attention to doing it well.

III. The Problems of Diversified Undertakings in Fishing Areas

In the fishing areas, there are both sea areas and mountains. Both abound with resources, which provide favorable conditions for us to develop diversified undertakings. We should regard the development of diversified undertakings in the fishing areas as a major task in implementing the production policies in the fishing areas and we should pay attention to fulfilling this task well in the same manner as we do to fishery.

There are quite a few advantages in developing diversified undertakings in fishing areas. First, it can provide many job opportunities for redundant laborers. Second, it facilitates the construction of the land base for fishery and will thus facilitate the development of fishery at seas. Third, the output of offshore fishery is not steady and it often fluctuates up and down. When it fluctuates down, the development of diversified undertakings can make up the decrease of income from fishery. This will enable our fishermen to have steadily increasing income and will therefore be an important way for the fishing areas to become rich. Fourth, it will enable the fishing areas to rely on their own strength to provide some materials and goods that are necessary for developing fishery. For example, 20,000 tung oil trees have been planted in Xiangshan County in the past few years and they will bear fruit in the coming 1 or 2 years. Pines have been planted on many islands in Zhoushan Prefecture and many of them have already grown into forests. The Dongwan brigade in Dinghai County has cultivated many mao bamboo trees, which grow very well. Now these bamboos can supply the needs of other brigades as well as all of the Dongwan brigade's own needs.

There are a large number of ways for developing diversified undertakings in fishing areas. We can either develop cutlivation of orange trees, grape vines, tea plants and bamboo trees or engage in breeding long-hair rabbits, otters and minks. We can also develop saltworks, food industry, transportation service, building materials industry and shell carving and other handicrafts. The Xiashan commune in Ninghai County is situated on 11 small islands. During the recent years, besides developing fishing and fish breeding, the commune has reclaimed 960 mu--nearly 1 mu per household--from beach and planted orange trees on it. These trees bore 240,000 jin of oranges last year. The commune has also utilized the local resources to set up a factory to process orange and aquatic products. Last year, the commune obtained 1.75 million yuan of income from this factory. It has also set up other commune enterprises such as stone pit and boat factory.

in 1981, of the total income of the commune 28 percent came from fishing, 29 percent from sea aquatic breeding and 43 percent from diversified undertakings. The average income per laborer was 776 yuan and that per capita was 378 yuan. Now, all the people above the age of 16 are employed in the production of the collective.

IV. The Problem of the Production Responsibility System

Judging by the forms of the production responsibility system that is being implemented in a few counties, there are the following three major forms of the production responsibility system geared to offshore fishery: The first is fixing quotas for output, cost and workpoints and granting rewards for overfulfillment of output quotas and for lowering costs. The second is proportionate division of profits. When this form is implemented, the means of production belong to the brigades but the production is organized by the operation units and the income is divided proportionately between the brigade and the units. The third is assigning full responsibility for fulfilling quotas to units, which are to organize the production and shoulder the responsibility for profits and losses under the unified accounting of the brigade and which should hand over a certain proportion of their profits to the brigade. All the localities and units that have implemented the production responsibility system are carrying out their production satisfactorily. The problem now is to vigorously pay attention to perfecting these forms of the production responsibility system in order to stabilize them.

As for the first form of the responsibility system, the major task for improvement at present is to rationally fix output quotas and the proportion of rewards and penalties and to strengthen cost management. In this respect, the Nanfeng brigade in Daishan County has done its work in a relatively satisfactory manner. The costs of production in this brigade are not charged to the brigade, but to the operation units that have been assigned cost quotas. The proportion of rewards or penalties in relation to profits and losses is 30 percent. Care of all production tools in boats have been assigned to specific persons. Thus it has achieved relatively good results in conserving on materials and goods and in lowering costs. Rewards for output in excess of the output quota have been raised from being 15 percent to being 20 percent of its value. In order to encourage the operation units to catch more second-class industrial fish, it has decided to pay a premium of 1 yuan for every dan of industrial fish that have been caught.

As for the last form of the responsibility system, the major problem we have to solve is to correctly handle the relationship between the unified management and separate assignment of responsibility. The Guoqing fishery brigade in Ningguo County has carried out its unified management by adhering to the principle that the means of production are owned by the brigade and all the manpower should be put under the unified arrangement of the brigade and to the principle that all the financial receipts and expenditures should be recorded in the consolidated account of the brigade and that all the units should follow the guidance of the state plan. At the same time, the brigade has also paid attention to raising the quotas of brigade accumulation funds, public welfare funds, depreciation provision funds and administration charge. In 1981, the brigade collected 86,000 yuan of the above-mentioned funds and charges, which was a 45 percent increase over the year before. The income per capita was 405 yuan, which was 34 percent more than that in 1980. The brigade sold 4,458 dan of aquatic products to the state, which was 21 percent more than in 1980. It has also replaced some old boats with new ones and thus increased its production capacity. These experiences should be vigorously popularized in all the other areas in the light of their local conditions.

V. The Problem that Concerns Scientific Research and Education

The results of the investigation in all the localities have shown that in the past few years our province has achieved some good results in its scientific research related to offshore aquatic production. For example, we have satisfactorily carried out an investigation of the offshore aquatic resources and made some trial improvement of motorized sailboats. Moreover, we have achieved certain results in breeding kelp, laver and prawns and in developing the comprehensive exploitation of black scrapers. All these have promoted the development of offshore fishery. However, taking the situation as a whole, our scientific research has lagged behind the production and has fallen short of the demands of the development of production.

At present, there are 15 offshore aquatic production research institutes and one aquatic production college in our province. We should further implement the policy of scientific research serving production. We should coordinate in carrying out of the general strategy of gradually extending our offshore fishery to outer offshore fishing grounds and soundly carry out research on the major tasks such as investigating outer offshore aquatic resources, outer offshore fishing, aquatic breeding, processing of aquatic products and scientific management. We should strive to achieve good results in the research and use these results in production as soon as possible. Regarding a few key research tasks, we should organize cooperation between different research institutes in order to make a breakthrough by their joint efforts. At the same time, we should correct the erroneous ideas in some of our research workers who attach importance only to scientific research and neglect the popularization of the results of their scientific research. We should conscientiously popularize and make good use of the results of our scientific research. For example, we succeeded in making some trial equipment for using the inertia of engines of motorized sailboats to heighten pressure and using the heat of the waste gas to conserve on energy. We have also succeeded in using the heat of the waste gas of diesel engines of motorized sailboats for cooking and for drying small aquatic products in motorized sailboats. All these results should be vigorously popularized.

It is reported by Wenzhou and Taishan prefectures that at present more than 50 percent of our fishermen, most of whom have been employed as fishermen in the past few years, are fishermen who rely only on the information provided to them by radio broadcasts in carrying out their fishing. These fishermen lack practical experience and often fish blindly. All the localities should pay close attention to training fishermen to master the skills of finding fish and operating fishing nets and to training fishery technicians. At the same time, they should make efforts to popularize cultural education and scientific and technical knowledge in fishing areas in order to train a new generation of fishermen to meet the demand of the socialist modernization of fishery.

'RENMIN RIBAO' DISCUSSES PLANNED ECONOMY IN AGRICULTURE

HK300346 Beijing RENMIN RIBAO in Chinese 27 May 82 p 5

[Article by Wu Zhenkun [0702 2182 0981]: "Several Questions Regarding Persistently Taking Planned Economy as the Leading Factor in Agriculture"]

[Text] The party has relaxed the rural economic policies and instituted various types of production responsibility systems in recent years. The results of this have been very good. Agricultural production has developed and the rural economy has been enlivened. However, a kind of misunderstanding has developed among certain comrades who think that state planning is apparently no longer needed after the institution of various types of agricultural production responsibility system, and that control by planning can apparently be relaxed since stress is laid on respecting the production teams' decisionmaking rights. The tendency to pay no heed to state plans has also emerged in certain places with regard to arrangements for cultivation plans and the monopoly and apportioned procurement of agricultural and sideline products.

In their crop cultivation, some places have inappropriately reduced the grain area and increased the area sown to industrial crops such as cotton, tobacco and oil-bearing crops. Of course, it is quite proper to switch to cultivating industrial crops on land unsuited to grain cultivation. The 1982 state plan aimed at controlling the tobacco cultivation area at 8 million mu this year (last year it was 8 million mu), but reports from all parts of the country indicate that the area may have reached 10 million mu. Production of rapeseed developed too rapidly last year, and the sown area this year tends to be still greater. The sown area of cotton has also been increased too much in some places. The loss of control over the cultivated areas of industrial crops will have two consequences: 1) There will be a continued decline in the grain area; the area sown to grain in the whole country last winter was 9 million mu less than in the previous year, and this will have an unfavorable effect on the effort to increase grain output; 2) excessively rapid development of industrial goods will bring about a situation whereby they cannot be harvested, processed, stored or transported, thus causing losses to the state and the peasants.

With regard to the procurement of agricultural products, the amounts procured have fallen continually in the past 2 years while more and more have been inappropriately bought at increased and negotiated prices after overfulfilling procurement quotas. This has affected market supplies and price stability and has also increased the state's expenditures. Although the base figure for national grain procurement has fallen, the figure has not been fulfilled in the past 2 years. Of course, a reduction in the amount of grain procured according to the base figure certainly does not mean that the state has procured less grain than in the past; what it does mean is that each year more grain is being procured at increased or negotiated prices. Last year only about 40 percent of grain was procured at par; the other 60 percent or so was bought at increased or negotiated prices. This meant a big increase in state expenditures on grain price subsidies.

Recently the peasants in some places have been unwilling to raise pigs. On the one hand this is because there are reduced or no supplies of feed grain, and on the other because there is less money to be made from raising pigs than from selling grain at increased prices, so they do not want to raise pigs even if the feed grain is there. At present there is a marked decline in pig procurement in certain provinces, and quite a number of towns have had no alternative but to restore the method of supplying pork in limited amounts. The peasants in the outskirts of certain towns are unwilling to cultivate vegetables according to the state plan because they all want to engage in money-spinning industrial production or other business. As a result vegetable supplies for the towns cannot be assured.

There are many reasons for the emergence of all these problems but a very important one is that the controlling role of the state agricultural plans has been lost. Ours is socialist agriculture, and it must persistently take planned economy as the leading factor and regard the whole country as a chessboard.

In light of the present situation, we should do well in solving in ideological understanding and policy measures the following problems, in order to uphold the principles of regarding planned economy as the leading factor and regulation by marketing mechanism as secondary in agriculture.

First, the agricultural economy is the main component part of our country's socialist economy and must be subordinate to guidance by the state plans.

China's socialist economy is planned economy based on public ownership; it is an economy that the state can consciously control in accordance with prearranged plans. Although there are differences in the degree of public ownership between agriculture and industry, while there is also some discrepancy in the nature of planning between them, they are both under public ownership and so for both of them there is the objective inevitability of developing in an planned and proportioned way. Industry and agriculture are interdependent.

If there are plans for industry but not for agriculture, the national economy cannot develop in a proportioned way. Moreover, agriculture is the foundation of the national economy, and whether agriculture can develop in a planned and proportioned way has a particularly important bearing on whether the development of the entire national economy in a planned and proportioned way can be guaranteed. Our entire socialist economic life can only be coordinated if agriculture develops in a planned and proportioned way and the grain, industrial crops and other agricultural and sideline products it provides can meet the various needs of social production and the people's life.

Some people say: "Since stress is laid on persistently taking planned economy as the leading factor, is it still necessary to respect the production teams' decisionmaking powers?" In fact, persistently taking planned economy as the leading factor is fundamentally identical with respecting the production teams' decisionmaking powers. The two can be completely harmonized. In addition to control and use of all their land, mountain forests, water conservation facilities, draft animals, agricultural equipment and tools and so on, and unified control and allocation of their manpower, the production teams' decisionmaking powers mean that they have the powers to carry out field cultivation in light of their local conditions, to decide on measures for increasing production, to formulate management methods, and to distribute their own income, and so on. However, the premise of decisionmaking powers is to accept guidance by the state plans. In practicing guidance by planning for agriculture, the state takes into account its own and the overall interests and also the interests of the collective and the peasants, thus integrating the three very well. Agriculture can only develop along the correct orientation by subordinating itself to guidance by the state plans, and also by making correct use of its decisionmaking powers and acting according to objective laws. If people divorce themselves from guidance by the state plans, lay onesided emphasis on decisionmaking powers, and carry out any activity that brings in money, this is bound to wreck the state's unified plans, cause imbalances in social production and chaos in social economic life. This will damage the fundamental interests of the state and also the collective and individual interests of the peasants.

There are also people who worry, "will laying stress on taking planned economy as the leading factor stifle the economy to death and lead us back to the old road?" It should be realized that the current stress on taking planned economy as the leading factor certainly does not mean that we want to go back to the old road. However, it is essential to bring the peasants' enthusiasm onto the track of the state plans, so that they will contribute to modernization under the guidance of the state plans. Moreover, our stress on taking planned economy as the leading factor certainly does not mean that we do not want regulation by market mechanism; what it does mean is that regulation by market mechanism should be correctly applied under the premise of taking planned economy as the leading factor. This is what is commonly referred to as "big plans, small freedoms." Only thus can the enlivenment of the economy be helped.

Secondly, correctly handle the relationship between developing grain production and developing industrial crops, and implement in an all-round way the guiding principle "actively promote diversification without the slightest relaxation of grain production."

For a long time in the past we simply promoted grain production and attached no importance to diversification. For this we suffered a lot. In the light of this historical lesson, in accordance with our national condition, and proceeding from developing agriculture in an all-round way and benefitting economic returns and ecological balance, the central authorities have put forward the guiding principle "Actively promote diversification without the slightest relaxation of grain production." In order to implement this principle in an all-round way, it is necessary to correctly understand and handle the relationship between developing grain production and developing industrial crops.

The central authorities have decided to import some grain every year in the future. This decision has been made in order to readjust the internal structure of China's agriculture and arrange it in a rational way, and in particular to ensure that those regions best suited to developing industrial crops can reduce their grain cultivation task to some extent and vigorously develop their industrial crops. In this way the economic returns will be better and the state, the collective and the individual will benefit more. Moreover, the amount of grain we can import each year is very limited. The 1 billion people can only solve their food problem by relying on their own efforts. Hence, we should develop industrial crops in a planned way under the premise of ensuring a steady rise in grain production. In this way there will be a general plan and rational arrangements for our agricultural production. We should first ensure that our annual grain output reaches a certain level, and secondly we must fulfill the state monopoly procurement quota stipulated by the plan. To ensure that these two planned tasks can be fulfilled, an extremely important material condition is necessary, and that is that the national grain cultivation area is stabilized at a certain figure. If the grain area is reduced, this is bound to affect the fulfillment of the plans for total output and procurement quota.

Taking the country as a whole, the proportion between the cultivation areas of grain and industrial crops is now basically rational as a result of several years of readjustment, and it is necessary to stabilize the grain area and avoid reducing it any more. The focus on the future development of industrial crops should be not on taking over grain land and squeezing grain aside but on improving yields and quality. For instance, the cultivation areas of tobacco and rapeseed should be strictly controlled according to the state plans, and efforts should be made to improve their yields and quality. In increasing the cultivation area of industrial crops and promoting diversification, we should focus our attention on making full use of sandy wasteland, alkaline land, abandoned farmland, and old pits and pools, and on making full use of extensive mountain, hilly and plain regions and the waters. We should guide the peasant masses to advance toward the depth and breadth of production. In this way both grain production and diversification will grow steadily.

Thirdly, it is necessary to take effective measures under the guidance of the state plans to promote production of vegetables and pigs.

Comrade Chen Yun clearly pointed out in 1957: "The significance of the problem of supplying vegetables and other nonstaple foodstuffs is certainly not less than that of building factories; the issue should be assigned a status of equal importance." This should become the guiding ideology for solving the vegetable problem for urban residents. To ensure that sufficient vegetables are planted according to the plan, and planted well, we must resolutely map out the vegetable cultivation areas according to the needs of the urban population and ensure that no more of the existing vegetable land is taken for other purposes. New vegetable land should be opened up in a planned way in places where too much of the old vegetable land has been occupied for other purposes. The outskirts of towns should practice the guiding principle of concentrating on vegetable cultivation and institute planned cultivation and procurement. The state-owned vegetable companies and the vegetable-growing production teams must sign contracts according to the state plans, stipulate reward and penalty clauses and also criteria for grain and fertilizer supplies, and mutually carry out their economic responsibilities. Vegetables are grown throughout the year and sent to market daily. The most suitable production responsibility systems should be selected in light of this characteristic.

Pig-raising tasks and procurement quotas should be formulated in light of state and local needs and assigned and mapped out for the production teams and households. The rural communes and brigades and the peasant households should actively develop pig-raising in accordance with the plans handed down to them, treating this in the same way as they do grain production. It is necessary to resolutely implement the reward and penalty policies on pig-raising stipulated by the state, and ensure that the peasants can gain proper benefit from pig-raising.

Fourthly, it is necessary to ensure the fulfillment of the monopoly and apportioned quotas for agricultural products and also the plans for allocation and transfer.

For a certain period in socialist construction, when supplies of many important agricultural products cannot meet demand, the state must continue to practice the monopoly and apportioned procurement methods in order to ensure the fulfillment of the procurement quotas for certain major agricultural products. The state monopoly procurement method is the policy of unified procurement practiced by the state for the agricultural products of grain, cotton and oil which have a very important bearing on the national economy and the people's livelihood. Agricultural producers must sell to the designated commercial organs the products stipulated for monopoly state procurement in accordance with the stipulated varieties, quantity and price, and the state handles these products in a unified way. Apportioned procurement is a policy by which the government apportions to the peasants a certain part of the task of selling some agricultural and sideline products that have a relatively important bearing on the national economy and the people's livelihood. With regard to the agricultural and sideline products for which apportioned procurement is practiced, the state only apportions a certain amount of the sales quota to the rural communes and brigades and the individual peasants, and the designated commercial departments procure them at the planned price. The targets for monopoly and apportioned procurement are the most basic targets in the state's agricultural production plans and have binding force. The main point in upholding planned economy as the leading factor in agriculture is to strictly carry out the monopoly and apportioned procurement policies and ensure the fulfillment of these procurement tasks.

The task of allocation and transfer of agricultural and sideline products, as planned by the state, must be fulfilled according to plan, in order to meet the needs of the state, ensure that large advanced factories using agricultural and sideline products as raw materials receive sufficient supplies, and gain still greater economic returns. Areas producing raw materials can only process or arrange other uses for these materials after the state delivery quotas have been fulfilled. Ensuring the fulfillment of the delivery quotas is also an important measure for persistently taking planned economy as the leading factor.

We should make a correct summation of the role played in enlivening the economy by taking planned economy as the leading factor and regulation by market mechanism as secondary. This summation should be made in light of historical experiences and especially the practice of recent years. We should realize that regulation by market mechanism has indeed played a beneficial role in enlivening the economy. Hence, in the future we should attach importance to this role of regulation by market mechanism. However, historical and current experiences all show that the key to enlivening the economy lies in having a comprehensively balanced economy plan that accords with reality. If planning control is lost, imbalances and market chaos will result, and regulation by market mechanism will be unable to play its role in promoting all-round balance; and if things are not handled well, this kind of imbalance might be intensified. If too much stress is laid on the role of regulation by market mechanism, our economy is bound to get off the track of planning and to be thrown into chaos. Hence, it is essential to uphold the guiding principle of taking planned economy as the leading factor and regulation by market mechanism as secondary in order to enliven the agricultural economy and the entire national economy.

INCREASE IN DISPOSABLE INCOME, CHANGE IN CONSUMPTION REPORTED

Beijing RENMIN RIBAO in Chinese 30 Mar 82 p 1

[Article from Xinhuashe, Beijing, 29 Mar: "City and Countryside People's Purchasing Power Has Increased 43 Percent During Past 3 Years. Party and Government Take a Series of Actions to Improve People's Livelihood"]

[Text] According to a report from JINGJI CANKAO [ECONOMIC REFERENCE], statistical data provided by the State Statistical Bureau shows that since the Third Plenary Session of the 11th Party Central Committee, as a result of a series of actions taken by the party and government to improve the people's livelihood, city and country residents' money income has tremendously increased, purchasing power has risen remarkably, and changes have taken place in the structure of consumption.

In 1981 total monetary value of consumer goods bought by city and country people increased 60.4 percent as compared with 1978. After adjusting for retail price increases, the rate of increase was 43 percent. The situation nationally of average monetary increase in consumer goods purchased during the 3 year period was as follows: 117.20 yuan in 1978, 135.20 yuan in 1979, 163.70 yuan in 1980, and 180.80 yuan in 1981. The increase in 1981 as compared with 1978 was 54.3 percent.

Rural purchasing power increased more rapidly than in cities and towns; however, in absolute money terms, cities and towns were still three times higher than rural villages. In 1981 rural residents' purchase of consumer goods (figured in money terms, and likewise in succeeding cases) increased 90.2 percent over 1978. For city and town residents, purchases of consumer goods increased 36.4 percent over 1978. In terms of population average, in 1981 rural resident purchases of consumer goods averaged 117.40 yuan per capita, a rise of 53.90 yuan compared with 1978, for an 84.9 percent increase. City and town resident purchases of consumer goods averaged 457.90 yuan per capita, a 93.40 yuan increase over 1978 for a 25.6 percent increase.

Among the consumer goods purchased by city and country residents, the increase was greater in clothing and items for daily use than for food and fuel.

Purchasing power increased more rapidly than growth of sources of supply, and cash surplus purchasing power became increasingly great. In 1981, sources of supply of consumer goods grew 53.6 percent over 1978 for the year, while consumer goods purchasing power increased 65.8 percent for the year, exceeding the speed of increase of sources of supply of consumer goods.

NOTICE ON COLLECTIVE INCOME DISTRIBUTION REPORTS

Beijing GONGSHE CAIWU in Chinese No 1, 6 Jan 82 p 5

[Article: "Ministry of Agriculture Notice"]

[Text] The notice issued by the Ministry of Agriculture on 20 November on reporting those production brigades and counties in which the average per capita collective distribution for rural people's communes in 1981 was above 300 yuan, and those counties in which it was below 50 yuan, as well as data from basic accounting units, required all jurisdictions henceforth to prepare statistics once annually, seeking the truth in facts, on production teams and counties with average per capita collective distributions of more than 300 yuan and on counties with less than 50 yuan, as well as on basic accounting units.

The following points constituted the principal content of the notice:

1. Beginning in 1981, production brigades and counties having an average per capita income of 300 yuan or more, counties in which it was 50 yuan or below and data about basic accounting units should form a major, integral part of the annual compilation work for the statistical reports on national rural people's communes earnings distributions, and [these data] should be statistically collated on an individual basis.

2. The per capita average of collectively distributed income, including bonuses, and commune and brigade enterprise wages not included in gross earnings of basic accounting units [should be reported].

3. Figures using production brigades as statistical units, including both those for production teams and production brigades, and figures using counties as statistical units, including production teams, production brigades and communes, [should be included].

4. Production brigades that have average per capita collective income of more than 300 yuan should, according to the circumstances of income distribution, be shown on an A-type chart, with (1) subcategory 1, subcategory 2, subcategory 3 and (2) subcategory 1, subcategory 2 items filled in, and the following items should be added:

(1) Total workforce (individuals), including the agricultural workforce, the brigade-operated industry workforce and the brigade-operated business workforce;

(2) Brigade-operated industry earnings and business earnings;

(3) Total cultivated land (mu), including amount for grain and amount for economic crops.

Data on afforestation should be compiled level by level. Every province, municipality and region should report by name those production brigades having average per capita earnings of more than 300 yuan, list the counties and communes in which they are located and the average per capita level of earnings distribution, and select experience summaries and tables showing the income distribution for some three to five brigades.

5. Statistical tabulations for counties with average collective earnings distributions of more than 500 yuan or less than 50 yuan per capita as well as for brigades with more than 300 yuan per capita, should be filled out by each county and reported to the provinces, municipalities and regions; no compilations are necessary.

METHODS FOR CALCULATING PEASANT HOUSEHOLD INCOME LISTED

Beijing GONGSHE CAIWU in Chinese No 1, 6 Jan 82 pp 13-14

[Article by Chen Huamei [7115 5478 5019], Yi Minghua [2496 2494 5478], Wu Baixing [0702 4102 5887], and Zhang Shichun [1728 0013 0193]: "How To Distribute Earnings in Production Teams in Which Peasant Households Assume Full Responsibility for Completion of Tasks"]

[Text] Forms of distribution depend on the form of the responsibility system. In production teams in which peasant households assume full responsibility for the completion of tasks, party distribution policies are carried out through contracts, and what is turned over to the state and kept by commune members is done through the contracting of full responsibility that reflects the "relationship among the three" [state, collective, and individual]. This is a change in the method of distribution which has been brought about by changes in the form of the economy. However, making an accounting of task completion when peasant households assume full responsibility can account for only that portion tendered the state in the system of sole responsibility for completion of tasks. One must also use statistical accounting to figure the portion retained by commune members, in order to reflect the results and the income distribution situation from production operations as a whole.

1. Checking and ascertaining receipts and disbursements. Brigades that practice a system whereby peasant households assume full responsibility for completion of tasks will still have to institute fiscal checking of money, grain, material receipts, expenditures and all economic transactions that are included in their ledger accounts, and they will have to determine the receipts and expenditures for portions retained by commune members. The scope of checking and of determining will for the most part include fields, industrial sideline occupations and economically diversified farming on fixed output quota land for which outputs will have to be ascertained and converted into output value. It will be necessary to check receipts and examine expenses, and both to check the collectively distributed portions and to figure amounts and output value of what is tendered to higher authorities and what is personally gained through the system of assumption of sole responsibility, in order to fundamentally reflect the overall picture of the collective economy. As for methodology, invoices are to form the data base for accounting for the portions included in the ledgers, for conscientious financial checking, verifying receipts and disbursements and ascertaining

disbursements. Representative sampling can be done in the case of portions in the system of peasant households that assume full responsibility for the completion of tasks; alternatively, a complete accounting may be done or a combination of the two may be used. Use of the former method entails selecting representative accounts for a check to see whether receipts are all right, usual or short, and whether expenses are high, normal or low, and [entails] checking to see whether the figures are substantially genuine and have statistical value. Use of the latter method entails starting with a summary of the production responsibility system, using reports from individual households and popular evaluations [minping 3046 6097], and household-by-household registration in a comprehensive accounting of the area of all crops and output, and of all receipts and expenditures. No matter which method is used, it is necessary to substantially reflect realities.

2. Honoring of contracts. In production teams which practice the system in which peasant households assume full responsibility for the completion of tasks, the carrying out of contracts means the carrying out of distributions, and the honoring of contracts means the honoring of distributions. At year's end, when contracts are honored, the settlement of accounts and the honoring of contracts must adhere to the principle of making readjustments for severe disasters but doing nothing about less severe disasters.

3. Preparation of earnings distribution forms. On the basis of extrapolation from accounts data in ledger and representative sampling, or on the basis of comprehensive accounting, all outputs and output values should be used to fill in forms on crop output (or output value), and these crop output (or output value) forms should be used to draw up grain distribution plans and total earnings distribution plans. On the basis of these two plans and commune member chits, commune member income distribution settlement sheets should be prepared.

4. Doing a good job of distribution account transfers. Following implementation of the system in which peasant households assume full responsibility for the completion of tasks, the monies and grain that commune members customarily turn over to production teams have been entered into transaction accounts and are no longer treated as income from farming, and no further distribution of them is made. Therefore, in the part that is turned over by commune members who have assumed sole responsibility, only a settlement of transaction accounts is made at the end of the year, with no need for transfer of distribution accounts. For the uniformly administered, collectively distributed portion, however, a relationship between earnings and distributions still exists, and after final accounts have been settled and distributions concluded, it is necessary to distribute transfer accounts on the basis of the collectively distributed portion of distribution plans. Transfers of accounts still must be included in the "earnings distribution" column. Following settlement and transfer of distributions, no balances should remain for debits in the "earnings distributions" column recording transfers of funds from columns having to do with income; for credits recording transfers of funds from columns having to do with expenditures; or for net income to the state, the collective and individuals in the earnings distribution plan.

ADMINISTRATIVE ACTIONS TO INCREASE ECONOMIC EFFECTIVENESS DISCUSSED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 1, 5 Jan 82 pp 4-5

[Article by Commentator: "Agriculture Should Take the Road of Improving Economic Benefits"]

[Text] Flushed with victory, we have strode into 1982. Not long ago, the Fourth Session of the Fifth National People's Congress passed Premier Zhao Ziyang's government work report. This is a programmatic document for our future guidance in doing a good job of economic work. This issue of the magazine has excerpted from this report the portions dealing with agriculture in the 10 articles on economic construction programs. We must diligently study and strive to implement them.

Agriculture is the foundation of the national economy. All-around development of the rural economy is the key in assuring all-around growth of the national economy. In accordance with requirements of the period of national economic readjustment, development of agricultural production or carrying out of rural construction in any given year in the future cannot rely on overly great increases in state investment in agriculture; rather most reliance will have to be placed on policies and science, hopes being placed on efforts to increase economic benefits. As Premier Zhao Ziyang proposed: "Use of every possible means to increase economic benefits in the individual fields of production, construction and circulation is a key problem"; "Our agriculture must take the road of fairly little investment for fairly high economic benefits."

Since the founding of the People's Republic, China's agricultural productivity has developed very greatly. In a country of 1 billion population, we have solved the problem of getting enough to eat and have supported the nation's socialist construction. This is beyond doubt a great feat. It must be realized at the same time, however, that the economic benefits of our agricultural production are still not high. Investment of labor is very much not matched by rise in labor productivity rates. During the past 30 years, the workforce engaged in agriculture has increased by 130 million to its present 300 million size, while the labor productivity rate has increased by only about 1 percent. The main reasons are the singular nature of production, over-centralization of management, no calculation of costs in operations and egalitarianism in distribution, which contravene natural laws and economic laws and create extremely great waste of manpower, financial and material resources and very poor economic benefits. Since the Third Plenary Session [of the 11th Party Central Committee], the aforementioned circumstances have begun to change, but very great efforts will still be required to effect fundamental turnaround.

Improvement of agriculture's economic benefits is a major topic with many problems requiring solution. Looked at in terms of current realities, the several problems below require serious attention.

First is further improvement of production responsibility systems, combining the bringing into play of the strengths of a collective economy with arousal of commune member enthusiasm, the collective economy thereby deriving inherent dynamism. In recent years, the broad masses of peasants and rural cadres have broken the fetters of "leftist" ideology to build diverse production responsibility systems, agricultural productivity thereby achieving yet another liberation. This is a marvelous reform and the fruits of this reform must be consolidated and developed. The Central Committee has clearly announced its adherence to the socialist collectivization, and long-term unchanged ownership system of ownership of the basic means of production such as land, and adherence to long-term unchanged production responsibility systems in carrying out collective agricultural economy. Acting in the spirit of the aforestated "two long-term unchange," we should strive to improve and perfect the various types of agricultural production responsibility systems. In order to do this, except for a minority of communes and brigades that have yet to establish responsibility systems or that have established responsibility systems but the masses are very dissatisfied, requiring continued building and readjustment, from an overall standpoint, no matter the form of responsibility system selected, all should be consolidated and gradually perfected on the basis of stabilizing the system. One problem that should now receive special attention is how to consolidate intermediate areas and intermediate communes and brigades. After 30 years of construction, these areas have varying degrees of public property and public facilities. In view of the malady of egalitarianism within their collective economies, the peasants urgently demand the practice of contracting. A fairly good method would be a system of collective management and control as well as contracting out for specialized jobs. The ingredients in a system of collective management and control and the form and extent must be arrived at through an adaptation of general methods to local situations and local industries; when local condition calls for collective management, then collective management should be applied, and when local condition requires assigning tasks to individuals or groups for completion, then contracts should be made. Additionally, another new situation merits attention, namely, now that the problems of food and clothing have been solved, peasants universally demand development of economic diversification to increase their earnings. Therefore, when production responsibility systems are improved and perfected anywhere, improvements should not be limited simply to farmland production. Attention has to be given to inculcation of a large-scale agriculture mentality, with consideration given to how to promote development of economic diversification, and to channel mass enthusiasm for production for in-depth and in-breadth advances in production, and the perfection of production responsibility systems, thereby meeting the needs of all-around development of farming, forestry, animal husbandry sideline occupations and fisheries.

Second is further readjustment and restructuring of the production structure for multiple kinds of operations, all-around development and increase in commodity production. In 1980 output value of farming was 73.9 percent of gross national output value of agriculture, the output value of forestry, animal husbandry, sideline occupations, fisheries and commune and brigade enterprises amounting to only 26.1 percent. Such extremely single-natured production must be changed. Agricultural production is a multiple production process requiring the coordination and cooperation of all its aspects in order to be uniformly mutually supporting and promote improvements in economic benefits. Therefore, it is necessary to continue to devote attention to readjustment and to the building of an equitable production structure. On the basis of agricultural resources surveys, agricultural zoning should be done, and general methods adapted to general situations to plan both grain production and an equitable mosaic of economic crops, forestry, animal husbandry and fisheries. Vigorous development of economic diversification should be done in the spirit of the Central Committee's 1981 document 13 to take the road of multiple increases in value from "procurement to processing to sales," through comprehensive agricultural, industrial and commercial operations. In addition, sensible arrangements should be arranged with all departments having a part in preliminaries to production and follow-ups to production that are closely interrelated with agricultural production, such as the production and supply of means of production, technical services, transportation, storage and processing of goods, finance and credit in order to promote increase in the economic effectiveness of agriculture.

Third is firm attention to scientific research and promotion of technology. Science and technology are production forces. Through the study and promotion of science and technology, we are able to make fullest rational use of resources and use the results of science and technology to directly convert potential productivity into actual productivity to gain greater economic benefits. The bumper cotton harvests in Shandong Province during the past 2 years, for example, are directly related to their general use of fine variety cotton, Lumian No 1. In 1980, Xin County in that province used nothing but Lumian No 1 for yields of 120 jin per unit of area, a 56.3 jin increase over the previous year in an ample demonstration of the power of promotion of technology. Now, following promotion of responsibility systems, peasant enthusiasm for the study and use of science is at an unprecedented height, providing extremely advantageous conditions for the extension of technology. All jurisdictions should fully realize this new situation and place scientific research and technological promotion in a truly important position, strengthen leadership, seek to breed and promote fine varieties, improve farming systems, change the composition of chemical fertilizer, practice sensible fertilization, produce highly effective pesticides of low residual toxicity and selectively promote applicable agricultural mechanization, striving to achieve more outstanding results, thereby effectively combining the fruits of modern scientific and technological research with China's fine tradition of intensive farming.

Fourth is full use of the effectiveness of existing production facilities. As a result of more than 30 years of construction, we possess a large amount of agricultural project facilities with a rather impressive potential. By simply strengthening management, using them sensibly and conscientiously tapping their potential, without spending much more money, considerable economic benefits may be gained. For some time during the past we increased attention to changing nature, but frequently insufficiently serious attention was given how to adapt to nature and how to make full use of existing project facilities. This situation will have to be changed in the future. Right now special attention should be directed to shifting the focus of water conservancy from the construction of the past to management, so that existing project facilities and water resources will provide greater benefits. In addition, as a result of production responsibility system arousal of peasant enthusiasm and an increase in the labor efficiency rate, a surplus of labor exists. In addition to development of economic diversification, attention must be given to investment of labor with organization of the masses to strive for efficient field water conservancy, planting of trees for afforestation, the building of roads and bridges and such small-scale capital construction in order to improve agricultural production conditions and promote all-around development of the agricultural economy.

Fifth is attention to reorganization of commune and brigade fiscal management and promotion of economic accounting. For a long period of time, as a result of inattention to fiscal management and economic accounting, laxness has been created in the system, records are not clear, production expenses are excessive; loss and waste of collective financial and material resources is serious, most funds are used up and economic benefits are very poor. In 1980, the State Council approved and sent forward, "Report on the Status of Financial Reorganization Pilot Project Work in Shahe Commune, Changping County, Beijing Municipality." On the basis of instructions from the State Council, many places conducted pilot projects for the reorganization of financial management, and a small number of places have elaborated such projects in turn, obtaining distinct results. However, nationally speaking, progress has been slow, and vigorous attention is required. The goal of commune and brigade fiscal reorganization is to inventory holdings, overcome chaos, strengthen systems, plug loopholes, increase income and conserve on expenditures to improve economic benefits. Consequently in the process of reorganizing fiscal management, all jurisdictions should help commune and brigade cadres set up economic accounting points of view for the gradual establishment of expense quota and cost accounting systems to study investment and output, to be concerned about ways to generate wealth, to accumulate wealth and to use wealth.

In order to increase economic benefits from agriculture, sole reliance on economic measures and technical measures will not work either. Ideological and political work must be intensified to increase the socialist, patriotic, and collectivist consciousness of the broad masses of cadres and people to assure a socialist orientation for economic activities and, through pooling the wisdon and efforts of everyone, to take a road of relatively small investment for relatively high economic results.

XINJIANG EXPERIENCES WITH PLASTIC MULCH IN COTTON-GROWING RECOUNTED

Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 2, 1982 pp 22-24

[Article by Gao Hua [7559 0553] and Li Zhirong [2621 1807 2837]: "New Technique For High Cotton Yields--Growing Cotton Using Plastic Mulch"]

[Excerpts] In 1979 China began to extend plastic mulch technique, with experimental growing of crops using plastic mulch beginning on a state farm in Xinjiang Province. The area was only slightly more than 2 mu that year, and the major crops were vegetables. Results were similar to those in Japan at the outset, namely a general increase in yields ranging from 30 to 50 percent. In 1980, plastic mulch was used for the growing of crops on somewhat more than 50 mu, its use expanding from vegetables to melons, peanuts, potatoes, grapes, fruit tree seedlings, poplar trees, and cotton. Results of the experiments showed that under Xinjiang Province's natural conditions, use of plastic mulch culturing brought about varying degrees of increased yields and increased earnings for all crops. At the outset, vegetable yields increased by from 40 to 90 percent; they reached market 17 days earlier than usual, and their output value increased by from 20 to 60 percent. For melons, yields increased by more than 60 percent; and for peanuts yields doubled.

In 1981, the Xinjiang Reclamation Area actively extended plastic mulch techniques to the growing of cotton, extending it to a 20,000 mu area for greatly increased yields per unit of area. Estimated yields were about 160 jin per mu, a doubling of the 80 jin average cotton yields per mu for the reclamation area as a whole, and a 50 percent increase in yields as compared with control areas. Average profits per mu were 60 yuan more than for places not using plastic mulch. In both south and north Xinjiang, tremendous increases in yields and in earnings were registered.

1. Mechanism and Results of Plastic Mulch For Growing Cotton

A look at production experiences everywhere in the use of plastic mulch to grow cotton shows that mostly during the early stages of crop growth the mulch provides the crop a very good environment for growth and development and necessary conditions.

(1) Increased warmth. The light energy of the sun's rays penetrates the plastic mulch to reach the ground beneath the mulch. Because the mulch

functions as a physical insulator, the soil cannot come in direct contact with the atmosphere, reducing opportunities for dissipation of heat through convection or in the form of moisture evaporation. As a result, temperatures rise quickly and high. According to data from 162 Regimental Farm in the Dacheng State Farm and Land Reclamation Bureau, between late April and late June, plastic mulched cotton fields were 4.6°C warmer than control fields at a depth of 5 centimeters, and 3.9°C warmer at a depth of 10 centimeters. After July, as temperatures rise and as the mulched cotton plants get tall, their stems and leaves growing vigorously and the area between rows closing with vegetation fairly early, the amount of light energy reaching the ground decreases and the difference in ground temperatures gradually declines or even becomes lower, and benefits from increased temperatures disappear.

In the Xinjiang reclamation area, temperatures are generally low during the period between sowing and sprouting of cotton, and changes in temperatures are fairly great. This directly bears on the early development of a full stand of plants and on growth of sturdy plants. It is one of the major reasons for low cotton yields. Because of the effect of plastic mulch in increasing warmth during the early stage of growth, this problem is pretty well solved.

(2) Conservation of water. Once plastic mulch is placed on the ground, the insulating effect of the plastic cuts off the exchange of water moisture with the atmosphere close to the ground, effectively controlling evaporation of soil moisture. At the same time, some vapor condenses into water forming beads of water on the under side of the plastic that drips back into the soil, moisture thereby being accumulated and stored in the soil's surface horizon, and loss of soil moisture being reduced. After the plastic has been put down, when the thermal gradient functions poorly, it promotes a steady movement upward in the soil of moisture from the deep horizon to increase the moisture content of the surface of the soil. Therefore, plastic mulch functions both to conserve moisture and to increase moisture.

(3) Improvement of the soil's physical properties, promoting transformation of soil nutrients. After mulching with plastic, because the soil no longer is directly impacted by rain falling at a rate of 9 meters per second in direct watering, the soil does not readily harden on top. In addition, the water vapor in the soil is expanded by heat and contracted by coldness in a repeated "expansion and contraction" movement that makes individual soil particles small, increases the size of fissures in the soil, and makes the soil friable. Measurements taken at the Shihezi Agricultural Institute showed a per unit weight for soil at a depth of from 0 to 30 centimeters to be about 0.1 gram per cubic centimeter less than for the control, and porosity to be from 3.8 to 5.7 percent greater than the control.

(4) Promotes Growth and Development of Cotton Plants

(1) The development stage is advanced. Survey shows the sprouting period for plastic mulch cotton plants to be between 4 and 7 days earlier than for the control; the onset of squaring to be between 13 and 16 days earlier, and the flowering period to be 12 to 14 days earlier. In consequence, a corresponding protraction of the effective growth period results, which is a

major element in the growth of sturdy seedlings and early development that produces increased yields.

(2) Much and rapid growth of root system. The rapid and healthy growth of mulched cotton root systems is particularly apparent during the seedling and the squaring stages. Observations of roots dug up on 20 June at the Shihezi Academy of Agricultural Sciences showed the main root of plastic mulch cotton to be 45.4 centimeters long as compared with 12.45 centimeters for controls. Roots on individual plants of the former numbered 29 as compared with 10 on the control. The average dry weight of individual plant roots was 0.93 grams for plants mulched with plastic as compared with 0.3 grams for controls, an increase of 47.6 percent.

(3) Speed of plant growth also rapid. Measurements taken at the 162 Regiment at Dacheng show a daily growth of 0.5 centimeters for the main stem of mulched cotton plants as compared with an increase of 0.1 centimeters for controls. During the squaring period it was 1.35 centimeters for the mulched plants, as compared with an increase of 0.55 centimeters for controls.

To summarize the foregoing, as a result of the early development, increased speed of plant growth and leaf division, the fairly great leaf area coefficient during the seedling and squaring stages, the strong photosynthesis, and the great accumulation of dry material, there is early squaring, early flowering, early bolling, early ripening, and high yields.

(5) Prevention of damage from salinity and alkalinity. Inasmuch as plastic mulch affects moisture movement in the soil, it must inevitably also affect the movement of salinity. In southern Xinjiang reclamation areas where soil alkalinity and salinity is fairly high, because of the sharp decline in water moisture evaporation in cottonfields mulched with plastic, accumulation of salinity in the soil's surface horizon was slow, amounts slight, the seedling death rate small, and the seedling preservation rate increased.

2. Major Techniques For Growing Cotton Using Plastic Mulch

The purpose of using plastic mulch in the growing of cotton is to improve the growth and development environment of the crop and to overcome disadvantageous factors to attain consistently high yields. But one cannot suppose that simply by using a sheet of plastic to cover the ground that it is possible to obtain consistently high cotton yields. It is also necessary to use corresponding advanced farming techniques based on the laws of cotton growth and development and local natural conditions to make fullest use of the role of plastic mulch in increasing yields.

(1) Good soil selection and sufficient fertilization. The growing of cotton under plastic mulch places fairly high demands on soil conditions. Moreover, soil fertility is the foundation for high cotton yields. Experience in producing cotton has shown that the central link in high yields is solution to the problems of sturdy seedlings with early development, steady growth and much fruiting, and prevention of bolting and early decline of plants. If soil fertility is inadequate, plants will be prone to weakness and early

deterioration, which will impair the benefits of increased yields realizable from the growing of mulched cotton.

When we extended the growing of cotton under plastic mulch over wide areas in 1981, serious care was given to selection of soil of high fertility on which the previous crops had been alfalfa, green manure, melons and vegetables, or wheat. Soils of low fertility were fertilized with between 6,000 and 10,000 jin per mu of base fertilizer. Before sowing (or before putting down the plastic), additional deep fertilization at individual layers was done using between 30 and 60 jin per mu of nitrogenous fertilizer and 20 to 50 jin per mu of phosphate fertilizer. For high yields from mulched cotton, a definite amount of fertilization must be done using nitrogenous and phosphate fertilizer, and the ratio of phosphate fertilizer has to be increased appropriately.

(2) Improved quality of land leveling and spreading of plastic. Increases in yields from cotton farming with plastic mulch is closely related to how well the plastic is put down, and how well the plastic is put down depends, to a very large extent, on how well the land has been leveled. Criteria for leveling the land are soil moisture, soil looseness, friability, evenness, flatness, and tidiness, and in the laying of plastic the three criteria of tightness, density, and substantialness must be practiced. In production anything in the way of technical requirements that is done well, increases warmth, conserves soil moisture, or eliminates weeds is good.

Acting on the basis of previous crop and soil, all units adapted general methods to local situations to raise ridges between fields or flatten them for the laying of plastic.

(3) Suitably early sowing in an effort to get sturdy seedlings that develop yearly. Because of the benefits of plastic mulch in increasing temperatures, ground temperature can rapidly reach the temperatures at which seeds sprout and put forth seedlings. Consequently, suitably early sowing can bring early growth of seedlings, early development, early squaring, lengthening of the period of effective boll formation on cotton plants, and full use of potential for increased yields of cotton. In 1981, the cotton that was down under plastic around 20 April produced seedlings at the end of April. Squaring began in May; flowering began in mid-June; and by early July at the beginning of summer, there were from three to five bolls per plant.

The period for sowing must be 7 to 10 days before late frosts, i.e. sowing before the season for frosts ends for emergence of seedlings after the season frost ends in order to avoid frost damage.

(4) Reasonably close plantings that are evenly spaced. Both root growth and above ground vegetative growth of plastic mulched cotton are rapid. The plants grow tall and close the spaces between rows with their vegetation early, leading to a shading of the fields. Thus, plant density must be somewhat less than for cotton grown without plastic mulch.

In laying out distance between rows, the method of large and small ridges (i.e. wide and narrow rows) is a fairly good one, using a distance of 60 to

70 centimeters between rows with each ridge having double rows (wide and narrow rows). The advantages in thus using plastic mulch are a saving in plastic, and a saving in labor, convenience in machine laying of the plastic, and convenience in carrying out irrigation, fertilization, insect control and such field work.

(5) Irrigation at the right time in the right quantity. Water is a rather variable element in the growing of cotton, the promotion or control of cotton growth being done through watering.

This year use of plastic mulch in the growing of cotton in Xinjiang Province reclamation areas will be expanded over 500,000 mu. This will represent an expansion from 3 state farm and land reclamation bureaus in 1981 to 10 state farm and land reclamation areas this year over a wide area. Cotton growing has to be done in a certain season, and during spring the time when plastic is put down and seeds sown is fairly concentrated; use of labor is substantial, and conflicting demands for labor are fairly strong.

METHODS FOR SPRING WHEAT WATERING, FERTILIZATION EXPLAINED

Beijing RENMIN RIBAO in Chinese 28 Mar 82 p 3

[Article by Reporter Wang Yougong [3769 0645 1872]: "Scientific Reform in Wheatfield Care. Zhang Jinxi [1728 6930 3556] and Zhu Dehui [6175 1795 6540] Successfully Experiment With 'Leaf Age Indicator Advance and Retard Method'"]

[Text] A series of simple, convenient, and remarkably effective new wheatfield care methods--"leaf age indicator advance and retard methods" are rapidly being spread in winter wheat growing areas north and south.

These new methods use the number of leaves (leaf age) that appear on the main stem of wheat during the first lunar month as an indicator for the adoption of watering and fertilization measures to promote their development or retard their growth for the purpose of increasing yields. Specifically this method consists of the following: Before the wheat's overwintering begins, winter irrigation (possibly combined with a top dressing of fertilizer) is provided to give a first push to assure that the soil will have sufficient moisture and nutrients following greening up in the spring. Following greening up, the soil is cultivated to conserve its moisture and to restrain growth for root development. Around the time that the fifth leaf from the bottom of the main stem begins to appear (but before stem extension), a top dressing of fertilizer and a second water is given to increase the spiking rate. During the stage when the third and fourth leaf from the bottom of the main stem appear, the soil is cultivated again to restrain seedling growth for root development, retarding leaf growth between joints at the base of the plant and at the top of the plant for the prevention of lodging. During the stage when the boot leaf or the second leaf from the top appears, which is the jointing and booting stage, another application of fertilizer and watering is done to promote development of large spikes. Taken together, this series of methods is called the "method three advances and two retards," and it has also been descriptively called the W-type method of care. If the soil is fertile, seedling growth vigorous, plant colonies fairly large, and soil moisture conditions immediately following the lunar new year rather good, the fertilization and watering before the leaves begin to stand up may be omitted, and the root formation period extended. In this case, the method is called the V-type method of care.

Wheatfield care measures show strong regionality. Because of differences in climatic conditions north and south, it is difficult to make hard and fast rules concerning the previously suggested various methods of care, or about climate and other natural phenomena of any given season. But if one is to require care "depending on the season, the place and the condition of seedlings," the masses will feel this is "not to the point," and hard to grasp. Can't a series of care methods of general applicability everywhere be found! Zhang Jinxi, director of the Crop Institute of the Chinese Academy of Agricultural Sciences, and Zhu Dehui of the Crop Institute of the Beijing Municipal Academy of Agricultural Sciences have worked since 1975 on wheat's biological laws, particularly on the growth and development relationships of leaf age and internal organs (such as roots, stems, tillers, joints, leaf sheaths, and spikes), as well as on the effect of care measures such as fertilization and watering at different leaf ages on the growth and development of individual organs. They discovered that the "residual of leaf age" may be better used as a universally applicable indicator of when to fertilize, to water, and to cultivate in spring care of wheatfields.

During 1979, this series of care measures was first extended over a wide area in suburban Beijing. In 1980, the Ministry of Agriculture included them among its key items for promotion, and during the same year, these methods were put to use on more than 1 million mu of wheatfields everywhere, both north and south. Experience has shown that if diligently applied, they can increase yields by between 10 and 15 percent. Recently at Wen County in Henan Province, an on-site "leaf age indicator, advance and retard method" meeting was held that was attended by people from Hebei, Shanxi, Shandong, Henan, Shaani, northern Jiangsu, Anhui, Beijing, and Tianjin. The masses have reported that this series of care measures has several advantages. One is that tending the wheat according to the look of the leaves is a clear indicator that is easily mastered. Second, as compared with former care methods, generally watering one or two times less can be done for a saving in water and labor, and a reduction in costs. Third, these series of techniques are able to effectively readjust soil moisture conditions and seedling condition, to promote tillering, and to prevent lodging. According to incomplete statistics, the demonstration and promotion area in the aforementioned nine provinces and two cities has been expanded to more than 3 million mu.

FUNGUS-RESISTANT PROTECTIVE COATING FOR PLANTS DEVELOPED

Beijing RENMIN RIBAO in Chinese 27 Mar 82 p 2

[Article by Reporter Yang Chuanchun [2799 0278 2504]: "Chinese Academy of Agricultural Sciences Successfully Develops 'Plant Disease Protective Coating'"]

[Text] After many years of effort, the agricultural meteorology research office of the Chinese Academy of Agricultural Sciences has successfully developed a "plant disease protective coating" to prevent powdery mildew and downy mildew of cucumbers, anthracnose and ring rot of apples, and such fungus diseases of plants, which is remarkably effective.

For many years, both in China and abroad, important research and development of chemical pesticides to control plant diseases has been accompanied by problems of pesticides with residual toxicity and plant diseases resistant to pesticides. In 1975, assistant researcher, Comrade Liao Zongzu [1675 1350 2469] in the agricultural meteorology office of the Chinese Academy of Agricultural Sciences, while in the process of studying control of moisture in soil and plants, began to develop a "plant disease protective coating," and conceived of using this high polymer compound that forms a membrane for spraying on the surfaces of plants to form a coating with tensile strength, but which is virtually invisible to the naked eye, thereby depriving oxygen and moisture to fungus that cling to plant surfaces, preventing fungus hypha from penetrating plant cells, thus achieving the goal of physically preventing plant diseases.

In 1980 after the development of "plant disease protective coating" was finalized, Beijing Agricultural University, Beijing Municipal Nankou Farm, and Dongsheng Commune in Beijing's Haiding District conducted field experiments. Last November at the Bajia No 1 Brigade in Dongsheng Commune, in a cucumber patch that had not yet developed downy mildew, they conducted controlled experiments using clear water, the pesticide aliete, and "plant disease protective coating." Results were a 48.5 percent incidence of disease for plants on which clear water had been used, a 3.5 percent incidence for plants on which aliete had been used, and a 4.7 percent incidence for plants on which "plant disease protective coating" had been used. This shows an effectiveness in preventing disease of the "plant disease protective coating" that rivals that of the pesticide. At the Qianbajia No 1

Brigade in Dongsheng Commune last year, cucumber yields were only slightly more than 2,000 jin per mu as a result of serious incidence of powdery mildew. This year, following spraying with "plant disease protective coating," yields increased to somewhat more than 4,000 jin per mu.

The coating formed by "plant disease protective coating" does not impair plant photosynthesis or normal growth and development. Raw materials for this coating are abundant within China, and it is suitable for assembly line production and large area use.

BRIEFS

PEST, CROP DISEASE--According to the general survey station for crop diseases and pests under the Ministry of Agriculture, Animal Husbandry and Fishery, due to unfavorable weather conditions in various localities, cotton aphids have been reported in Hubei, Jiangsu, Anhui, Shaanxi, Shanxi, Henan, Shandong and Hebei provinces since last May. Hubei and Shaanxi are most seriously hit. Besides, rice blast has become prevalent in Fujian, Guangdong, Guangxi, Hunan, Jiangxi and Zhejiang provinces. The station called on various provinces to pay good attention to field inspection in order to prevent crop diseases in June. [OW271247 Beijing Domestic Service in Mandarin 1000 GMT 26 May 82 OW]

PRODUCTION MANAGEMENT UNDER CONTRACT SYSTEM DISCUSSED

Beijing GONGSHE CAIWU in Chinese No 1, 6 Jan 82 pp 28-30

[Article by Nanchong Prefecture Agriculture Bureau: "Survey of Production Team Collective Property Management Situation When Output Quotas Are Linked to Individual Able-Bodied Laborers, Output Quotas Are Fixed for Households and Peasant Households Assume Responsibility for Task Completion"]

[Text] We recently conducted a survey of production team property management when output quotas are linked to individual able-bodied laborers, output quotas are fixed for households and peasant households assume responsibility for the completion of tasks. All jurisdictions did a large amount of work in production team collective property management, exploring and accumulating many new methods and new experiences which play a definite role in the maintenance of the rural socialist collective ownership system. These methods were as follows:

1. Management of the raising and use of plow oxen. All jursidictions proceeded from convenience of animal use and helpfulness in protecting collective property, and adopted general methods to local situations, using diverse methods. The specific methods were: 1) Specialized people raising the animals and specialized people using them with stipulated tasks, signing of contracts and fees being charged for raising and using animals for cultivation. The First Production Team of the Fourth Production Brigade in Dongguan Commune, Nanchong County, has eight oxen, use of which is allocated by the commune. Eight people are in charge of feeding the oxen, and two plowmen are permanently assigned to each ox. Fees are collected for raising the animals and for using them in farming. Annual compensation collected for the maintenance of each draft ox amounts to 134 yuan (including sums paid for raising them, for their use in plowing and for their manure). Plowmen receive a fee of 4 yuan for every mu they cultivate (four plowings and four harrowings). 2) Plow oxen are sold at a converted price to commune members who are able to raise and use them, in a combination of nurture and use. Contracts are signed, and when oxen are used for cultivation, fees are collected. The First Production Team of the Third Production Brigade of Jinfeng Commune, Nanchong County, sold five oxen at converted prices to five commune members, the funds received going into public accumulation funds deposited in a special production-team savings account. A cultivation fee of 1.20 yuan per mu is charged for dryland, and 1.50 yuan per mu per

cultivation is charged for wetland (2 yuan per mu during the extremely busy season). Once an ox has been engaged by a household for cultivation and a contract has been signed, should any party refuse cultivation he is liable for payment of half the cultivation fee. 3) When plow oxen are turned over at a converted price to several households for their joint use, the several households are to raise payment funds in common, clearing the account within 3 years. Payment for the ox reverts to public accumulation funds and is deposited by the production team in a special account. 4) When a specialized household raises an ox for use in common by several households, a value is assigned the plow ox, and its use is guaranteed for a fixed number of years. The funds are taken in for depreciation each year (and deposited in a special account). If the ox is used longer than the specified number of years, a bonus goes to the production team; if the ox does not last for the specified number of years, the production team pays an indemnity. The Second Production Team of the Fifth Production Brigade in Linglong Commune, Yingshan County, has 21 plow oxen specially raised by 21 households and assigned to user households. Green grass for the oxen was cut by the hosueholds that raised the oxen, and straw was figured on the amount of the fixed output quota--half a jin of straw for the oxen being turned over per jin of output--with the ox manure being divided according to the fixed output figure. Workpoints for raising the oxen could be used for a share of money but not for a share of grain. 5) An ox was assigned user households, several households using the ox in common and taking turns caring for it. The plow oxen were assigned a value and a period of years of use set, with the production team collecting depreciation fees each year (for deposit into special accounts). If the number of years of use was exceeded, production teams received a bonus; if less, they paid an indemnity. Households lacking resources to raise oxen engaged someone to help them feed one; they had to provide the hay for the ox, but were not entitled to any of the ox manure.

2. Management and use of industrial farm implements, machinery and tools. These are generally not only small farm implements, small farm tools and utensils that are really of no use to production teams but have been assigned a value and sold to commune members, with the handling being done according to their original cost following discussion and agreement at a commune member meeting followed by approval from the commune, but also other large- and medium-size farm implements assigned a value to protect the investment in them, and a number of years of use established, for which a depreciation fee is collected annually (and deposited in a special account); a bonus is paid if they exceed the specified number of years of use, while an indemnity is paid if they do not last that long. Plows and harrow that are paired with oxen, waterwheels, winnowers, threshing buckets, threshing machines and such large- and medium-size farm implements used in common by several households (or individual compounds) are maintained by a special person who is paid a reasonable remuneration according to a reward and penalty system. Large- and medium-size grain drying and storing equipment, such as sunning mats, board storehouses, chests and barrels, as well as tools used for capital construction of farmlands that are in excess of quantities needed by or are not useful to production teams and are maintained by a specific person, may be rented to commune members or assigned

a value and sold to them. The Eighth Production Team of the Fourth Production Brigade in Linglong Commune, Yingshan County, fixed limits for use of all the large- and medium-size farm implements in the production team, assigned a value to them so as to protect the investment in them, fixed a number of years of useful life for them, and collected depreciation fees for them year by year (the fees were deposited in a special account). A bonus was paid if they exceeded the set useful life, and indemnity was paid if they did not. All the utensils, facilities and capital construction equipment used by the production team for grain storage were put in a storage room under control of the production team head, and bonuses were paid or penalties levied on the annual compensation paid the 30 workers who looked after them on the basis of how well they were maintained.

Machine equipment was invariably under unified production team use arrangements and could not be dismantled, damaged or sold. The methods used were as follows: 1. Machinery assigned for sole use by teams or individuals on contracts for net earnings to be turned over to production teams. The Third Production Team of the Sixth Production Brigade in Changle Commune, Nanchong County, contracted out a hand tractor, a rice thresher and a grinder to individuals, annually receiving from the contractors a net profit of from 350 to 450 yuan for the production team; maintenance fees were the responsibility of the contractors, and no workpoints were given. 2. Rental of machinery to individuals and individual accounting, and earnings divided up. The Third Production Team of the Sixth Production Brigade in Banzhu Commune, Nanchong County, rented a noodle-making machine to an individual who borrowed 300 jin of wheat from the production team as initial capital. Individual accounting was done, with 40 percent of the net profits going to the production team and 60 percent going to the individual. The production team provided no expenses and recorded no workpoints. 3. Rental of machinery to individuals with collection of rental contract fees. The 11th Production Team, 13th Brigade, Chengguan Commune, Nanchong County, rented a noodle-making machine to a person, annually collecting from him 60 yuan in rental contract fees.

3. Public building management and use. The production team's public buildings, including industrial sideline occupation plant buildings, maintenance buildings, pigstyes, cattle sheds and high-temperature buildings and cellars, a small number of dangerous buildings or unusable thatch buildings excepted, could generally be dismantled or sold at a converted price, following discussion and agreement by the masses and agreement by the commune, with the proceeds going into public accumulation funds. Use of the portions not going into special credit cooperative accounts would be arranged by the production team. Some of it was used to operate collective industrial sideline occupations or saved to maintain collective assets and resources. Some was used for production team conference rooms and classrooms, or to operate schools or other welfare endeavors. Some was loaned to commune and brigade enterprises or to commune members, with the rental funds reverting to the production team. Whoever occupied a building was responsible for keeping it in repair, and dividing it up was not permitted. The Seventh Production Team of the 12th Production Brigade in Boyang Commune, Feng'an County, rented to an orange team, and to a commune member

household each room of a three-room storeroom (a tile-roofed building) as a generator room, collecting 5 yuan a year per room in rent. It also rented a three-room pigsty (with a tile roof) to three separate commune families with a large number of people whose house was crowded. The Eighth Production Team of the Fourth Production Brigade in Linglong Commune, Yingshan County, continued to use the production team's large high-temperature room to keep sweet potatoes for commune members; the head of the financial team was put in charge and received 50 workpoints in compensation each year. Each year a single household could store 18,000 jin in the cellar in a large bamboo basket with excellent results.

4. Management and use of sunning grounds. The range of uses was generally assigned on the basis of the sunning ground situation. The Seventh Production Team of the 12th Production Brigade in Boyang Commune, Feng'an County, assigned sunning grounds in conjunction with threshing buckets; the masses were very pleased.

5. Management and use of water conservation facilities. All jurisdictions attached great importance to water conservancy facilities such as ponds, reservoirs and weirs, generally managing them very well. Responsibility systems for management and use of water were also rather well implemented. It was in water storage fields where problems were fairly numerous. So that existing water storage fields would continue to play a role and not be adversely affected because of changes in responsibility systems, the action that many communes and brigades took was as follows: 1) They made water storage fields into publicly owned fields under the control of the production team and individually contracted them out, but established a strict system of water management and water use. 2) They appropriately adjusted downward target quota criteria for water storage fields and contracted them out to commune members. After lowering by 10 percent the target output criteria for two water storage field plots (4 mu), the 11th Production Team of the 13th Production Brigade in Chengguan Commune, Nanchong County, contracted them out to commune members. 3) As a result of production team administration of water storage, everyone benefited equally. In the First Production Team, First Production Brigade, in Heping Commune, Nanchong County, the production team administered the water storage, and every household invested funds and planted seedlings; every person delivered four buckets of liquid manure, 1 dan of ash fertilizer and 1 jin of urea to the water storage field, the output being divided among all.

6. Management and use of forests. The general method for managing and using forests was as follows: For economic forests in single tracts, a system of specialized contracting with remuneration linked to output was put into effect with rewards and penalties for overfulfillment or underfulfillment of contracts. For lumber forests in continuous tracts, management by specialized teams or specialized personnel was instituted in a "four fixed" responsibility system of fixed personnel with fixed duties, for fixed remuneration and fixed rewards and penalties. For scattered woodlands on large areas of land for which production was contracted, the woodlands were made a part of the land contracted to commune members for management, and a system instituted of either payment of fixed output quotas to higher authority or division of earnings.

HIGH OUTPUT OF ECONOMICALLY DIVERSIFIED GOODS ENCOURAGED

Lanzhou GANSU RIBAO in Chinese 31 Jan 82 pp 1, 2

[Article: "Decisions On Development of Rural Economic Diversification by Gansu Provincial CCP Committee and Gansu Provincial People's Government"]

[Excerpts] From 2 to 7 December 1981, the Provincial CCP Committee and the Provincial People's Government held a provincewide conference on rural economic diversification. The conference diligently summarized and exchanged experiences during the past 2 years in the province's development of economic diversification, compared advanced prefectures in the province in a search for disparities, and studied further implementation of the guiding spirit of the CCP Central Committee and the State Council on development of rural economic diversification. Below appear the decisions taken on problems relating to development of rural economic diversification in Gansu Province.

1. Continued Solution to Problems of Ideological Perception, Devoting Efforts to Development of Economic Diversification as a Strategic Task in Making the Rural Economy Flourish

Ever since the Third Plenary Session of the 11th Party Central Committee, and particularly following issuance of CCP Central Committee Document No 13 (1981), all levels of the party organization and people's government in Gansu Province have attached great importance to the job of developing economic diversification, and have made definite accomplishments. A change has begun in the internal structure of agriculture, and output value from economic diversification as a ratio of gross output value of agriculture climbed from 38 percent in 1979 to about 45 percent in 1981. However, our mentality has not been sufficiently liberated and our hands and feet are not yet fully free as regards problems in development of economically diversified production. The single crop mentality of some places has not been fundamentally turned around. We must make up our minds to solve problems in these regards and to do a solid job of carrying economic diversification forward.

2. Devoting Attention to Programming and Planning Work For Planned Step by Step Development of Economically Diversified Production

In order to advance economic diversification, a program that seeks truth in facts and inspires people must exist. The province's programming, led by the

Provincial Agricultural Commission, and the joint responsibility of the Agricultural Planning Commission, the Financial Office, and the Planning Commission is to be put forward before the end of June 1982. Programs for economically diversified production are to be carried out simultaneously with natural resources surveys and agricultural zoning. Programs and plans are to proceed from realities, highlight one's own strengths, and take other factors into account. Program criteria and annual plans must simultaneously take into consideration factors such as the raising of funds, technical conditions, natural and labor resources, and relationship between supply and demand. They must make full use of the province's strengths in abundant labor resources and plentiful natural resources, and accomplish much with the spending of little money.

In formulating programs, all prefectures are to give development of the livestock industry and forestry a strategic position in the transformation of the structure of agricultural production. The potential for development of the livestock industry is very great in both pastoral and agricultural areas, and a myriad households are able to engage in it. The planting of trees and the growing of grass is one of the key points in transforming the basic conditions for agricultural production in Gansu Province, and are also major projects for development of economic diversification. All jurisdictions should attach extremely great importance to the building of economic forests, timber forests, and fuel forests. While continuing steady growth in grain output, the area for growing of various economic crops should be suitably increased. Rural villages should actively develop on-site processing, selection, and comprehensive utilization of agricultural sideline products. Rural processing industries, unlike various large industries that compete for raw materials, duplicate plant construction, and give extremely great attention to economic benefits, will have their programs coordinated with communes and brigades by departments in charge for step-by-step development to avoid blindness in action.

Development of economic diversification requires full arousal of the enthusiasm of both the collective and individuals. The collective should do whatever the collective should properly do, and peasant households or an assemblage of several commune member households should engage in whatever is suitable for individual commune members to do. In undertaking economic diversification, the collective should set projects, should reserve the land, the forestland, and the wasteland necessary for development of economic diversification, should regularize workforces, and should follow the principle of producing what can be conveniently produced and whatever is beneficial, unifying whatever lends itself to unification, and decentralizing whatever lends itself to decentralization. All kinds of specialized units, teams, households, and industries should be established, and contracts that "fix quotas, contract production or tasks, and provide rewards" used to do a good job of collective economic diversification. For items that are to be under the purview of individual commune members, communes and brigades should actively organize and support the genuine bringing into play of the role of myriad households, males, females, the old, and the young. When projects are jointly administered by several households of commune members, the principle of voluntary participation and mutual benefit must be adhered to; rules and regulations to be jointly honored should be formulated, and matters handled strictly in accordance with regulations.

Provincial CCP Committee and Provincial People's Government regulations on the delimiting of "three wastelands" for the use of commune members should continue to be implemented. Places meeting conditions should be delimited to the maximum extent possible for commune member use, ownership of trees and grasslands planted by the masses belong to whomever planted them with no change for a long period of time.

Vigorous advocacy and active support should be given commune member household sideline occupations. Units concerned should provide fine varieties, enhance technical guidance, increase capabilities for storage, hauling, and processing, and enliven commodity circulation channels. Encouragement should be given to working to become prosperous. Effective action should be taken and support given to hardship households to help them develop production so as to change their straitened circumstances with all possible speed.

Vigorous support should be given households specializing in planting, breeding, and processing, and to development of a jointly managed economy. The appearance of various kinds of specialized households and jointly managed economies makes a fine start in agriculture's movement toward specialization and socialization, and marks a new point of departure for the modernization of agriculture. Specialized households and jointly managed economies should be given political encouragement, technical guidance, and financial and material support in the fields of supply, production, marketing and hauling, and should be treated in the same way as the collective economy.

Commune and brigade enterprises are a major force in development of rural economic diversification, which should continue to be readjusted and diligently reorganized to bring about genuine change in the chaotic situation of indiscriminate meddling, arbitrary egalitarianism and indiscriminate transfer of resources, and corruption and misappropriation, to further correct the orientation of production, focus operations on the processing of agricultural sideline products, and to promote development of the planting and breeding industries to provide society commodities of diverse kinds.

Good management and good use should be made of funds from all trades and industries for the support of agricultural sideline production, and building of bases should be intensified to promote development of commodity production.

4. Active Development of Scientific Research and Technological Development Work For an In-Depth and In-Breadth March Forward in Production

All levels of agricultural research units and related research units should place economically diversified production on their daily agenda. They should widely develop research activities on the basis of actual needs for development of economic diversification in order to serve production. They should diligently summarize the accumulated experiences of the masses in the practice of production. They should particularly promote, with great vigor, those projects requiring little expenditure of money, that show quick results, and that have high economic value.

Agricultural science departments and related units should establish direct relationships with economically diversified specialized units, teams, and households, signing technical contracts for prevention and control of epidemic diseases, breeding of fine varieties, imparting of technical skills, and for processing and storage. State-owned agricultural, forestry, and livestock farms should also actively breed fine varieties of breeding animals, breeding poultry, eggs for hatching, and seedlings and saplings required by society to supply needs. All who make outstanding achievements in this regard should be given commendations and rewards.

5. Under Guidance of State Plans, to Give Attention to Bringing Into Play the Regulatory Role of Markets and Encouragement to Development of Economic Diversification

In the development of rural economic diversification, adherence must go to the dominant role of the socialist planned economy in bringing into play the regulatory function of markets.

(1) All economically diversified products in the unified procurement or quota procurement category should be provided for in contracts signed by state-owned commercial units or supply and marketing cooperatives with production units or individuals. The contracts should clearly set forth responsibilities and be strictly honored. Under usual circumstances, whenever a party fails to live up to a contract, thereby causing losses for other parties, the other parties have the right to demand payment of economic compensation. In case of dispute, industrial and commercial administrative and management departments should mediate, and when mediation is ineffective, the courts may arbitrate.

(2) In the case of unified procured and quota procured products, departments concerned are to refer to the actual average procurement figures for 1978, 1979, and 1980 to establish equitable base figures for procurement to remain in force for several years. In cases where it is difficult to set base figures for certain kinds of goods, an equitable ratio between procurement and retention should be set. After unified procurement and quota procurement tasks have been fulfilled, except for those goods for which the state has stipulated that market trade should not be permitted, all other goods may be traded in markets by producing units, or may be purchased by the state at negotiated prices or exchanged for scarce industrial goods.

(3) All agricultural sideline products that have piled up in the hands of the masses as a result of mistaken guidance plans should be bought back at market prices, and new marketing avenues actively opened for them. For goods that are in oversupply as a result of blind production, pertinent departments have responsibility for helping the masses find marketing outlets, reducing, insofar as possible, losses to producers.

(4) In order to promote development of economic diversification, all jurisdictions can establish commune and brigade collectively operated trade warehouses. Trade warehouses could purchase and sell goods left over after centralized procurement and quota purchase tasks have been fulfilled; could organize communes, brigades, and commune members to process raw and processed materials, and have sole selling rights for their products; and could organize their own sources of supply, within the scope permitted by state plans, to satisfy market demand.

(5) Some individual business households and joint production, hauling, and sales businesses should be revived and developed. They should be linked to state-owned businesses, or to supply and marketing cooperatives, and be organized for door-to-door sales in the countryside. They could also set up retail outlets in cities and towns to do both buying and selling, themselves being responsible for profits and losses. Economically diversified production units and processing units could operate shops behind or in front of plants, for the sale of their own products, and they could skip intervening links to sell the products they produce directly and face to face. Industrial and commercial administrative departments should give them the green light for this, issue business permits and, except in cases of those engaged in profiteering and illegal sales of prohibited items, they should not arbitrarily interfere.

(6) Price problems. Since the Third Plenary Session of the 11th Party Central Committee, the state has raised procurement prices paid for agricultural sideline products, and it has made some needed readjustments in procurement policies as a result of which the peasants have gained very great benefits. It is necessary to stabilize these effective and workable policies, and in order to take care of the vested interests of the peasants, to assure continued steady development of agricultural production. Owing to the current national financial situation, for some time in the future a policy of basic stability will be followed in procurement prices paid for agricultural sideline products. Increases in peasant earnings cannot be expected to come from increases in procurement prices paid or from a lowering of procurement base figures but rather can come only primarily from reliance on the development of commodity output and the selling of a large quantity of goods in great demand.

BRIEFS

DIVERSIFIED ECONOMY--The Qingyang branch office of the Chinese Agricultural Bank has vigorously supported communes and brigades and commune members in developing diversified economy. In 1981 the office loaned 1,100 commune members some 280,000 yuan to help them develop household sideline production, enabling them to make 410,000 yuan income in 1 year. Since 1980 the office has released 261,000 yuan of loans to set up 63 cattle farms. The office has also financed the establishment of commune- and brigade-run enterprises and some service businesses. In 1981 the office was able to withdraw 4.09 million yuan of agricultural loans, 70 percent of the total loans issued. [SK301115 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 28 May 82 SK]

GAOTAI COUNTY ECONOMY--Gaotai County of Gansu Province has substantially developed diversified economy. Last year, the county's income from developing diversified economy reached 14 million yuan, 25 percent higher than in previous years. The county's grain acreage has stabilized at 220,000 mu. Some 2,000 mu of saline-alkali lands have been used to plant sugar beets, and some 5,000 mu of farmland have been returned to forestry departments. TORRENTIAL RAINSTORMS REPORTED OVER

HK030337 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 2 Jun 82

[Text] In recent days Zhuhai municipality has had its heaviest rainstorms in 80 years. In 3 days beginning on 28 May, rainfall at (Sandao) commune, where precipitation was the heaviest, reached 935 mm. Dangerous situations arose at five reservoirs in the municipality. Thanks to heroic crash-repair work carried out by the cadres and masses and the local PLA, the dangers were all eliminated.

From 28 May to 2 June, heavy rain, torrential in places, fell throughout Huiyang Prefecture. Rainfall was about 300 mm in Boluo, Dongguan, Huiyang and Huidong counties and Huizhou municipality, in the southern part of the prefecture. By 2300 hours on 2 June, the water level on the Dongjiang at Huizhou was 12.91 meters. The danger mark is 13 meters. The flood-crest level is expected to reach 14 meters at about 2000 hours on 3 June.

According to the provincial meteorological station, the heavy and torrential rains that fell throughout Guangdong at the end of May and the beginning of June are now over. The heavy rain began in the northwest part of the province on 27 May. According to incomplete statistics, heavy rainstorms occurred in 79 counties. Maximum rainfall in a 24-hour period occurred in Zhuhai, Huilai, Shanwei township in Haifeng, and Doumen. Fourteen countries and municipalities had more than 100 mm of rain in a day.

According to an analysis of meteorological data, the major rain area over the province moved southeast on 2 June, where it weakened and dissipated. Thus the heavy and torrential rains of the past 7 days are over. The province will have no heavy rain on 3 and 4 June.

BRIEFS

SPRING HARVESTING--Guangzhou, 25 May (XINHUA)--Guangdong Province has completed harvesting of spring crops. The province reaped 1,173,000,000 jin of spring grain, up 2.18 percent from the 1981 yield. The province this year has increased soybean production by 20 percent, tobacco by more than 10 percent and vegetables by a big margin, as compared with last year. MOBILIZATION OF FORCES TO FIGHT DROUGHT SURVEYED

Notice Issued

Shijiazhuang HEBEI RIBAO in Chinese 13 May 82 p 1

[Article: "Provincial Military Region Political Department Issues Notice Calling on Subordinate Units and Masses of Militia To Join at Once in the Struggle of "One Resistance and Two Guarantees"]

[Text] On 11 May the Provincial Military Region Political Department issued an urgent notice requiring subordinate units and militia throughout the province to take action at once in a determined response to the provincial CCP Committee's and the provincial government's call to join actively in the fight against drought and to contribute forces to spring plowing and production in Hebei Province to win a bumper summer grain harvest.

The notice pointed out that drought conditions in the province are now extremely serious and pose a serious threat to spring planting and wheat growth. It required all levels of military units to handle as a central task the organization and mobilization of militia in joining the struggle "to resist drought and guarantee spring planting and summer harvesting." It also required centralized planning of all work under the guidance of CCP committees to assure smooth progress in the fight against drought. Cadres at all levels in military units are to go down onto the frontlines of the fight against drought, and work shoulder with the militia in fighting drought.

The notice required intensification of political ideology work among the militia. Militia are to be organized for conscientious study to implement the "Summary of Minutes of the National Rural Work Conference," and for further improvement of various forms of production responsibility systems. Militia are to be taught to overcome a passive mentality of waiting for rain to fall from the sky, to build up their confidence in combating frought to win a bumper harvest, to carry forward a spirit of self-reliance and arduous struggle, and fully to use prevailing conditions to do a good job of fighting drought, doing spring planting, and caring for the wheat.

The notice required subordinate organizations and military units actively to organize manpower and material to support local fights against drought. Military unit farms and production sites are to carry forward their fine style and accomodate the masses; they may not compete with the masses for water or for advantage. In the course of supporting local areas in fighting drought, military units should help the dependents of martyrs and servicemen as well as households enjoying the five guarantees [childless and inform old persons who are guaranteed food, clothing, medical care, housing and burial expenses by the people's communes] to carry on production in order to further cement relations among the government, the armed forces, and the people.

Additional Efforts Urged

Shijiazhuang HEBEI RIBAO in Chinese 13 May 82 p 1

[Article: Provincial CCP Committee and Provincial Government Leading Comrades Go Deep Into the Frontline of Struggle Against Drought. Conscientiously Investigate and Study, and Diligently Strengthen Leadership.

[Text] In order to win total victory against drought to preserve the summer harvest and to protect spring sowing, recently the provincial CCP Committee decided that organizations directly subordinate to the province should transfer a group of cadres led by principal leading comrades in the provincial CCP Committee and the provincial government to go deeply into the frontline of the struggle against drought, to further guide and give impetus to the launching of a extensive struggle against drought in all jurisidctions.

Among the comrades in charge from the provincial CCP Committee and provincial government who went to the frontline were Jin Ming [6855 2494], Wang Zheng [3769 6927], Guo Zhi [6753 1807], Yang Zejiang [2799 3419 3068], Wang Dongning [3769 2639 1380], Wang Kedong [3769 0460 2639], Li Yongjin [2621 3057 6651], Yang Naijun [2799 0035 0193, Li Feng [2621 6912], Xu Ruilin [1776 3843 2621], and Han Qimin [7281 0796 3046]. An additional 17 comrades in charge of offices, commissions, agencies and plants, and youth and women's organizations directly subordinate to the province went.

Hebei's drought continues and has become extremely serious. Most prefectures have had 4 years of continuous drought, and in some places the drought has gone on for 5 years. Major waterways have stopped flowing, and reservoirs and ponds have dried up. The water table has fallen by a general 2 to 3 meters or by as much as 4 or 5 meters. Additionally, since the beginning of May several six or seven degree windstorms have struck, which have not only made the drought situation more serious, but have also been extremely bad for the wheat and cotton. As a result of the drought, cotton sowing plans could not be fulfilled in some places, and more than 10 million mu of crops that should have been sown in the spring will now be sown in the summer. In some places death from drought, lodging, and parching of the bootleaves of wheat is rather severs. On 11 May, faced with serious drought, the provincial CCP Committee and the provincial government separately convened a mobilization meeting to go down to the countryside to fight drought. Taking part were comrades in charge of various departments, branches, committees, and offices. They called upon comrades going to the countryside to become closely involved with realities, investigate and study, and unite closely with the masses. They should help grassroots cadres concentrate their major efforts and attention on fighting drought; help feeble and lax grassroots teams quickly carry out reorganization, rally spirits, and actively lead the masses in launching a struggle against drought; and help grassroots teams formulate strong measures for countering drought, particularly establishing and perfecting pump well irrigation responsibility systems. In places where rain has fallen, the masses should be aroused to take advantage of soil moisture to rush planting, to check on cotton seedlings, and add seedlings where there are gaps.

Editorial Pep Talk

Shijiazhuang HEBEI RIBAO in Chinese 13 May 82 p 1

[Editorial: "Be Determined To Win Complete Victory in 'One Resistance and Two Guarantees'"]

[Text] "Beginning of summer" [around 5 May] has passed, and the province's struggle to resist drought to guarantee a summer harvest and to resist drought to guarantee spring planting has come to a crucial juncture. At this critical time, party and government leaders at all levels should be personal models, go personally into the frontline of the struggle against drought, and use every available means to come to grips with the present struggle against drought. They should strive for good wheat and cotton harvests this year, and lay a good foundation for winning an all around bumper harvest in agriculture this year. This is extremely necessary.

This year's drought in Hebei Province follows on the heels of 4 to 5 years of continuous drought. Last winter and this spring little snow or rain fell. This plus consecutive years of drought has meant a great decline in the amount of water in storage everywhere and a great drop in the ground water table. Some reservoirs and ponds have dried up; watercourses have ceased to flow, and in a small number of villages, drinking water for people and animals has become a difficult problem. Recently high winds have blown continuously for several days causing tremendous evaporation of moisture from the soil. Now more than half the province's total land area has been stricken by drought, and some wheat has developed incompletely because of the drought. Some cotton, peanuts and spring sown food crops such as potatoes have not been planted on time, and some that have been planted have not cropped up. Some of the seedlings that have come up have been parched to death by the drought or winds. Faced with serious drought, all levels of CCP committees and government throughout the province must make "one resistance and two guarantees" the central task in rural work. All other work must center around and be linked to this central task.

It must be clearly realized that though great achievements were made during the previous period in the struggle against drought in the province, difficulties are still very great and the drought situation continues to sorsen. Winning complete victory in resisting drought to guarantee the summer harvest, and resisting drought to guarantee spring planting will still require arduous efforts over a long period of time. We cannot be the slightest bit complacent o let down our guard. Nor can we slacken our fighting will because a little rain has fallen in some places during recent days. Even less can we lose confidence or be in a state of inertia in the face of hardships. We are now less than a month away from the summer harvest, and party and government leaders at all levels must recognize fully their serious responsibilities in fighting disaster to win a bumper harvest. They must recognize fully the major economic and political significance of further efforts to launch a struggle to resist drought and disaster to win a summer harvest and a bumper harvest for the year as a whole. They must continue to work ceaselessly and unremittingly, and carry forward a revolutionary spirit of not fearing weariness and continuing to fight, to fight resolutely, this battle of "one resistance and two "guarantees." Whether or not this year's wheat harvest will be slightly larger will be determined primarily by the per thousand weight of grains. If the per thousand weight of grains increases by 2 or 3 grams, the harvest for the province as a whole will increase by from several hundred million to more than 1 billion jin. Consequently, it is important conscientiously to intensify care during the late stage, doing a good job of watering, controlling aphids, spraying phosphate and guarding against hot dry winds. Right now much remains to be done in spring planting, and very soon the time for summer planting will be at hand. The time for planting is extremely limited. All jurisdictions must seize the favorable conditions that the rains of recent days provide to sow replacements for cotton plants, to sow oil-bearing crops, and to give strict attention to spring planting of grain. Once all crops have been planted, prompt checking and placement of seedlings will be required. Where soil moisture is insufficient, watering to resist drought will have to be done promptly to assure full stands of sturdy seedlings. Right now the struggle against drought is extremely hectic. All jurisdictions must continue from transfering large numbers of cadres during the previous stage to the further transfering of large numbers of cadres to the countryside. It is particularly important that leaders at all levels go down to the grassroots to become involved in production and to mingle with the masses to assure a centralization of leadership, a concentration of energies, and a concentration of manpower, financial, and material resources for unflagging struggle against drought.

Practice in many areas has shown that the key to effective struggle against drought lies in the arousal of revolutionary spirit among leadership teams. Currently a substantial number of grassroots level leadership teams everywhere are lax and weak. Though the personnel in these teams are perfectly all right, they are unable to carry out their responsibilities, do not dare work courageously, and work at matters profitable to individuals but pay no attention to matters that are not profitable. Healthy trends find no encouragement, and evil influences are not curbed. Data demonstrates that grassroots cadres are frequently lax and weak as a result of leadership not being clearly defined, attitudes not being forthright, and no vigorous support being given by superior authorities when difficulties arise. Consequently solution to the problem of laxness and weakness in grassroots leadership teams must begin with out leaders. Leaders at all levels must arouse a revolutionary spirit, unswervingly carrying out the four basic principles, and implement the lines, programs and policies that have followed from the 30 Plenary Session of the 11th Party Central Committee. On matters of great right and great wrong, they must take a clear stand without fear of offending anyone. Comrades who uphold principles, conscientiously discharge their responsibilities, actively work, and work without let up, should be given commendations and support. Those cadres who abandon their posts and who lack spirit must be criticized and indoctrinated. One must dare to halt unhealthy tendencies and dare to punish violations of the law or contraventions of discipline. All jurisdictions should affirm accomplishments in previous periods in the struggle against drought, seek out shortcomings, comment the advanced, put the spur to the laggards, further arouse the enthusiasm of the broad masses of cadres and the people, be determined, eliminate countless difficulties, and win a complete victory in "one resistance and two guarantees."

After leaders at all levels have gone onto the frontline of resistance to drought, they must bond closely with the masses, perservere in investigation and study, and conscientiously resolve existing problems. They must use the method of "grasping matters at both ends to hold everything in between," on the one hand giving attention to advanced units, summarizing experiences, analyzing typical cases, and giving across-the-board guidance, while on the other hand devoting attention to units facing great difficultues and having numerous problems, prescribing remedies case by case, solving existing problems straightaway in some cases, and arousing the masses to struggle against drought. Where teams are lax and weak, cadres should be dispatched to stay and solve problems. Where responsibility systems are not complete, strenuous efforts should be made, in the course of the struggle against drought, to perfect them. Almost one-third of the province's production teams have not yet established responsibility systems for well and pump management. This is a major problem for which the masses urgently demand solution. All jurisdictions must direct a high degree of serious attention to this problem and diligently devote strict attention to solving it.

At the present time the jobs to be done in the struggle against drought are arduous, but advantageous conditions for our triumph over drought are also very numerous. These consist principally of the deep penetration into people's minds of the lines, programs, and policies of the Third Plenary Session, the unprecedently high surge of enthusiasm on the part of the broad masses of cadres and people for great efforts toward the four modernizations, plus experiences over several years in a row of fighting drought to win bumper harvests. So long as leaders at all levels inspire enthusiasm, unite the masses, actively work, and make concerted efforts, the disaster situation and losses can be reduced to the lowest minimum and an all around bumper harvest can be won in agriculture this year.

Cotton Sowing Efforts

Shijiazhuang HEBEI RIBAO in Chinese 14 May 82 p 1

[Article: "Rapidly Start an Upsurge in Checking on and Augmenting Cotton Seedlings"]

[Text] As a result of stubborn struggle against drought on the part of the broad masses of cadres and people in cotton-growing areas, a decisive victory has been won in the sowing of cotton throughout the province as a whole. Now, in addition to continue to wind up cotton sowing, it is necessary to make full use of favorable conditions following the rain to shift the focus rapidly to the checking of seedlings and adding seedlings where required for a full stand of cotton, and to continue to work ceaselessly and unremittingly to win victory in the battle for a full stand.

It must be realized that ever since the beginning of April there has been little rain and much wind plus continuing drought, and that some cottonfields have lost soil moisture and become parched. In some places, cotton sowing quality has been poor and sowing techniques not up to the norm. In cottonfields almost everywhere gaps among the seedlings or cracks in the ground around seedlings has taken place. This poses a very great threat to winning a bumper cotton harvest. It has been estimated that if 10 percent of seedlings in the province's cottonfields are lost, that would be the same as a 1 million mu reduction in the cottonfield area and would mean a 50 to 60 million dan decrease in ginned cotton. In the face of this situation, at all levels leaders positively cannot be paralyzed and negligent or view matters lightly. They are to indoctrinate the broad masses of cadres and people to carry forward a style of continuous combat and after completing cotton sowing go on to unremitting efforts without shirking to start an upsurge at once of checking and filling in gaps among seedlings to assure full stands.

It must be pointed out that because of force of habit in considering a more or less complete stand of crops as a full stand, some places do not fully understand the matter of a lack of a full stand and do not act quickly to correct it. Some other places suppose that sowing quality has been good and are blindly optimistic. Still other places have a sense of hopelessness when they see there are numerous missing seedlings and that the drought is so severe. Leaders at all levels must do thoroughgoing and meticulous political work, explain advantages and disadvantages clearly, and buttress conscientiousness about checking on and replacing missing seedlings for a full stand.

All levels of leaders must take in hand the task of assuring a full stand of seedlings in the same way that they took in hand the fight against drought to do planting. They msut brace themselves to combat drought to assure a full stand of seedlings, and adapt general methods to local situations to carry out technical measures to assure full stands. In cottonfields where seedlings have difficulty in emerging because of loss of soil moisture, prompt action should be taken to dig ditches to irrigate and replenish soil moisture. In drought stricken cottonfields suffering serious lack of soil moisture requiring that water be carried and seeds be dibbled, soil moisture should be supplemented by sinking wells for irrigation water. Where 50 percent or more of seedlings are missing in a cottonfield, the cotton should be destroyed at once and replanting done. The fields should not be planted to other crops. For cottonfields missing less than 50 percent of seedlings, forced budding of seeds for additional dibbling, or supplemental transplanting of shoots should be done to assure a full stand of seedlings. Wherever a plant is missing, one should be added; and wherever one has been added, it should be kept alive. In addition, cotton aphids should be eliminated and pests controlled at once.

Rush To Plant

Shijiazhuang HEBEI RIBAO 13 May 82 p 1

[Text] Following rainfall, all levesl of leaders in Chengde Prefecture have organized the masses of commune members for a concerted use of time and forces to rush to plant while the soil is moist. As of 7 May, the prefecture had sown more than 4.3 million mu of open field crops, dibbling or drilling seeds on more than 480,000 mu for a more than 90 percent fulfillment of sowing plans. During late April and early May, Chengde Prefecture had three light to medium rainfalls that provided soil moisture over a fairly wide area. The chengde Prefecture CCP Committee and government administrative offices thereupon issued urgent telegraphic notices to all municipalities and countries requiring all levels of leaders to take advantage of this favorable opportunity and give tailor-made guidance for the rush planting of the fields with soil moisture, planting main crops with all possible speed. They were to put water down and dibble seeds into the ground on fields lacking or having insufficient soil moisture. The prefecture fielded more than 3,800 cadres to go down to the frontlines to help improve work and gain frsthand experience in communes and brigades, to organize spring planting, and to hasten the pace of planting. Right now Chengde Prefecture is both winding up spring planting, inspecting and adding seedlings to blank spots, and is getting ready to transplant more than 100,000 mu of paddyfield crops.

HEBEI

TESTING OF NEW FARM CROPS, TECHNIQUES OUTLINED

Shijiazhuang HEBEI RIBAO in Chinese 11 Apr 82 p 4

[Article: "What Research Is Being Done on Agricultural Science and Technology in the Province This Year?"]

[Text] Recently the Provincial Science Commission convened a symposium on agricultural developmental research, which studied and made arrangements for this year's developmental research plans for new agricultural techniques and new results. This year Hebei Province's agricultural developmental research is characterized in the following ways: It is more closely centered around key problems in agricultural production and development. While positively not slackening grain production, it actively develops economic diversification, intensifies scientific and technical work in intermediate and low yield areas, and promotes balanced increases in output.

The number of counties and municipalities engaged in research projects for agricultural development this year has risen from last year's 22 to 47, and research projects on economic diversification have also increased. Demonstrations and experiments on new agricultural techniques and new results have increased from last year's 45 to 60, and the area of the experimental zone has expanded from somewhat more than 610,000 mu to 1.45 million mu. The major techniques and results explored and summarized this year are: Demonstration experiments using fine wheat varieties Beimai No 9, No 6, and Changle No 5, Cangsan No 1 corn, and "shallow fertilization of wheat with a mixture of nitrogenous and phosphate fertilizer"; verification and exploration of fine variety summer and autumn crops, and of bumper harvest transplanting techniques suited to the Heilonggang area and to planting in other dry, infertile, and alkaline soils; demonstration experiments of new strains of fine wheat varieties Zhenmai Nos 1 and 2, "74531," and Jimai No 7, new corn combination Hanza No 1 (Handan No 2), as well as "wheat leaf-age indicator promotion and control methods," and scientific use of water and fertilizer; verification and exploration of summer and autumn fine varieties suitable for growing in intermediate and high yield areas, and overall farming techniques for "high yields, consistent yields, and low cost."

2. Demonstration experiments on new cotton varieties Jimai No 2, Hanmiao No 5, and 7315, with exploration and verification of cotton varieties native to the province that are superior to Lumian No 1 in bumper harvests, resistances, and

fiber quality. In order to make full use of light and heat resources in central and southern Hebei and to increase output value, demonstration experiments were conducted using beer barley or early ripening wheat as a first crop and new varieties of early ripening cotton variety "Zhongmiansuo No 10" as a second crop; exploration and summarization of the continuous cropping of double high yield farming techniques. 3. By way of turning to advantage millet's tolerance of drought, demonstration experiments were conducted in the water-deficient areas of Zhangjiakou, Chengde, and Cangzhou on new strains of fine variety millet such as Jigu No 3, and summarization done of high yield techniques for growing it on dry, infertile, or alkaline soil. 4. In order to make full use of most of Hebei Province's low yield area resources and increase economic benefits, demonstration experiments were conducted using new strains of fine varieties of oil-bearing crops such as peanuts, flax, and sunflowers, on balanced increases in yields from fruit trees, on development of small livestock, and other economic diversification. 5. By way of rendering service to cities and industrial and mining areas, emphasis was placed on demonstration experiments with new varieties of watermelons in suburban areas and on farming techniques using small rounded plastic ground mulch enclosures; and on demonstration experiments on the use of fine hybrid vegetables.

ASSISTANCE GIVEN TO LEADERSHIP IN PRODUCTION TEAMS, BRIGADES

Shijiazhuang HEBEI RIBAO in Chinese 9 Apr 82 p 2

[Article by Dong Jiqin [5516 4949 0530]: "Ninety-Seven Percent of Handan Prefecture Wheatfields Have Been Watered. Assistance Given Grassroots To Intensify Building of Leadership Teams To Promote 'One Resistance and Double Contracts'"]

[Text] In view of problems of weakness and laxity existing in leadership groups in some production brigades and production teams, and the state of paryalysis or semiparalysis existing in a small number of "brigade and production-team teams" which adversely affects the launching of a movement of "one resistance and double contracts," Handan Prefecture's CCP Committee, and CCP committees in all counties in the prefecture have transferred 1,287 cadres to form work teams assigned to individual communes and brigades to help intensify the grassroots' building of leadership teams. In their reorganization of teams they have concentrated on the adaptation of general methods to local situations and the giving of tailored guidance on the basis of prevailing realities. In "fragmented teams" where, for lack of understanding about responsibility systems people first lock horns and then do as they please, they first intensified ideological education so that the people would define the limits of "double contracting" [the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion], and of dividing fields for individual working, increase their understanding, and take the initiative in assuming responsibility. In the case of "gloomy teams" that have not adjusted to the new situation, that cannot use old methods and will not use new methods, methods were taught and measures prescribed to improve their leadership skills. For "soft teams" in which individual resistance and lying down on the job was encountered in the carrying out of state policies and in maintaining the collective economy, clear support was given to make them straighten their backbones and work courageously. For "losing teams" that had made no provisions for cadre allowances, prompt and equitable solution was found and fair remuneration was worked out for this year. For "corrupt teams" that had disobeyed laws and violated discipline by occupying collective property the views of the masses were solicited, and resolute changes made in persons selected.

After work had been done for a period of time, 3,529 paralyzed and semiparalyzed brigade and production-team teams were reorganized. This was 88 percent of the total number. In 77 percent of the production teams in the prefecture, systems of personal cadre responsibility were established and perfected. This vigorously promoted the campaign to combat drought in spring farming. As of the end of March, the prefecture had activated 30,000 pump wells and watered 3.6 million mu of wheatfields, which was 97 percent of the wheatfield area. Yongnian, Linzhang, Cheng'an, Daming, and Handan Counties have fulfilled their wheat watering tasks and are now increasing the watering of dryland wheat. More than 1.1 million mu of fields in the prefecture were not plowed following last year's harvest, almost double the amount for the same period last year.

BENEFITS FROM CORN, SOYBEAN INTERCROPPING EMPHASIZED

Shijiazhuang HEBEI RIBAO in Chinese 9 Apr 82 p 2

[Article by Wang Fengwen [3769 7685 2429], [illegible] Yongqing [? 3057 1987], and Li [illegible] [2621 ?]: "Intercropping of Grain and Beans Is a Way To Develop Soybean Production"]

[Text] Soybeans are an agricultural crop of high economic value. They contain abundant protein, fat, many minerals and vitamins. They are a grain, an oil-bearing crop, a livestock feed crop, and their root nodules play an additional beneficial role in fixing nitrogen; thus, they are a very good crop for nurturing the soil. How can the province's soybean production be revived and developed as quickly as possible without impairing total grain production? A current look at numerous representative experiences shows that promotion of the intercropping of grain and beans, particularly the intercropping of corn and soybeans, is a way of developing the province's soybean production.

The intercropping of grain and beans lends itself to actual conditions prevailing in the province. Ours is a province with large population relative to available land in which grain supply is a large problem. Cultivated land in the province is currently less than 100 million mu, only 70 million mu of which is a grain growing area, or an average of slightly more than 1 mu per capita. In some places the amount is less than 1 mu per capita. Under these circumstances, except for a small number of places in which the amount of land is great relative to population, it is impossible to devote substantial acreage to the growing of soybeans alone. However, the province produces relatively small amounts of soybeans, and supplies are scarce, so development of soybean production is genuinely needed. Under these circumstances, the intercropping of grain and soybeans is a rather good way of truly resolving this contradiction.

Economic benefits derived from the intercropping of grain and soybeans are fairly outstanding. For example, in Cang County where the soil is saline and of low fertility, intercropping of corn and soybeans on 145,000 mu last year increased corn yields by an average 12.7 percent as compared with the cropping of corn alone. In Qing County, intercropping of corn and soybeans on 16,000 mu produced increases in yields averaging between 5.3 and 12.8 percent. In Luanping County, intercropping of corn and soybeans on 13,000 mu produced combined yields of 1,063 jin per mu. Figured on the basis of procurement prices paid for second grade, this meant an output value of 155.99 yuan per mu (including the value of byproducts), an increase of 24.15 yuan over the value of corn grown as a single crop. In addition, it was possible to regulate cropping to increase soil fertility and lower costs. Root nodule bacteria on soybeans are numerous, and they are able to fix large quantities of free nitrogen from the air. Soil on which soybeans have been grown not only produces increased yields in the same season, but also produces increases the following season for a total increased output for the year.

Intercropping of grain and soybeans makes for convenience in field care. When corn and soybeans are intercropped, crops with tall stalks and short stems naturally result in a matching of a member of the grass family with a member of the pulse family. The distance between corn and soybean rows is fairly wide, which makes for not only good ventilation and light penetration, a high energy utilization rate, and ease in making use of rows at the edges of fields for corn, but also makes for comparative ease in watering, fertilizing, cultivating, and weeding the fields, as well as for prevention and control of disease and insect pests.

When promoting intercropping, attention should be given to the solution of the following technical measures.

1. General methods should be adapted to local situations to set equitable proportions of corn and soybean rows. Practical experience with production shows that corn should predominate in corn growing areas, the proportion of corn rows to soybean rows being generally about 2:2, 3:3, 4:3, or 4:4. Such a method can assure high corn yields, and more soybeans can be harvested too. In some low yield areas, the proportion of soybeans may be increased somewhat, the ratio of corn to soybeans being 2:3, 2:4, or 4:6, so as to be able to harvest somewhat more soybeans.

2. Corn and soybean planting norms and sensibly close planting should be assured. In intercropping where corn predominates, the number of cornstalks should be no less than the number of cornstalks per mu when corn is grown as a single crop, and between 6,000 and 8,000 soybean plans is the right number In intercropping in which soybeans predominate, the requisite number of soybean plants per mu should be maintained to assure soybean output.

3. Suitable varieties should be selected. Corn varieties selected should have medium tall stalks, narrow leaves, permit good light penetration, and have great potential for increased yields. Soybean varieties selected should be early maturing, tolerant of shade, have compact plants, good bumper yield properties, and strong resistance to diseases and insect pests.

4. Strengthening of scientific management. If results from the intercropping of corn and soybeans are to be increased and large output assured, prompt attention must be given the prevention and control of insect pests. Special attention must be given to high yield areas. Experience in production has demonstrated that when intercropping is done, where conditions for soybean growth are poor and resistance to disease and insect pests of individual plants is weak, the natural regulation capacity of plant colonies will also be poor and disease and insect pest infestations fairly serious, impairment to output

being apparent. Consequently, attention must be given to treatment of seeds before they are sown to prevent underground insect damage and early spring insect damage. Aphids, dodder, insects that eat the hearts out of crops, and such diseases and pests must be diligently prevented and controlled so as to protect plants, preserve output, and increase benefits derived from intercropping.

DIVISION OF FARMLAND FOR CONSUMPTION, COMMODITY PRODUCTION PROMOTED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 1,
5 Jan 82 p 22

[Article by Sun Jingqi [1327 2529 4388], Shen Yuzhou [3088 3768 3166] and Bai Zhongyue [4101 0022 2588]: "Others Contract Farming of Grain Ration Fields While Farmers Farm Commodity Fields"]

[Text] In the process of strengthening and improving agricultural production systems of responsibility, Qing County in Hebei Province has made repeated experiments and comparisons for active promotion of a combination of people other than farmers contracting the farming of "grain ration fields," and farmers contracting the farming of "commodity fields" in a "two-field system." Now, more than one-third of all production teams are practicing this system.

Principal Ingredients and Methods of the "Two-Field System"

The masses call "grain ration fields," "self-sufficiency fields." On the basis of the natural population's annual average per capita grain ration needs, fields are designated on the basis of their yields, each person receiving from 0.5 to 1 mu for which they are assigned total responsibility, farming to be done by households that take care of their own grain ration needs, with no change for a long period of time. So long as they assure self-sufficiency in grain and oil, commune members may adapt general methods to local situations to farm as they please. On the basis of prevailing conditions, production teams provide maximum support in plowing, irrigation, fine variety seeds, chemical fertilizer, pesticides and processing of agricultural sideline products. Except for payment of agricultural taxes and a small amount of animal fodder, all the produce from "grain ration fields" reverts to households. As population increases or decreases, no change is made in the number of mu of land assigned. At a certain time in response to mass demands, necessary readjustments can be made. Households lacking workforces that can contract are sold a basic grain ration at distribution prices by production teams. Dependents of martyrs and military men who have no workforce, and "households enjoying the five guarantees" [childless and infirm old persons who are guaranteed food, clothing, medical care, housing and burial expenses] are not assigned "grain ration fields," but are taken care of out of public welfare funds.

"Commodity fields" are also known as "responsibility fields" by the masses, and consist of the major part of the land, grain ration fields excluded, which is contracted to the workforce that is expert at farming and specialized in agriculture whose forces are concentrated for development of commodity grain, edible oil, melons, fruits and vegetables. Depending on production conditions and management levels in different production teams, the commodity field contracting methods may be "several fixed and a single reward," contracting production or contracting work, or uniform distributions from set quotas everything in excess going to the producers. Alternatively, large-scale assignment of sole responsibility may be the method used, or specialized contracting with calculation of compensation linked to output may be used. No matter the method adopted, unified planning and leadership by production teams is to be emphasized, with attention given to making the most of collective strength. Commune members not suited for contracting in agriculture or those who possess other special skills do not have to contract, or can contract fewer "commodity fields." They will be assigned by the production teams to other collectively organized industrial sideline occupations, or to other specialized teams, specialized households, or specialized work. All economic income received by those contracting in other trades has to be divided up and accounted for in the practice of large-scale assignment of responsibilities or proportional division. In some cases workpoints will be recorded for sharing in uniform distributions. Those without economic income such as electricians, schoolteachers in civilian schools, or barefoot doctors, should practice fixed rewards and penalties for fixed duties, allowances being provided them from the earnings of each economic specialty so that they have the same level of earnings as those doing the same kind of work or in the same workforce category.

Practice Has Shown that Despite Its Present Lack of Perfection, the "Two-Fields System" Has Evidenced Distinct Superiorities. First, it is advantageous both for grain production and for economic diversification. During the past 3 years, the province's gross output of grain has averaged 209 million jin, 20 million jin of which was annually contributed to the state, and 30 million jin of which was retained by collectives as seeds or for livestock feed, commune members' grain rations amounting to 150 million jin or more than 70 percent of the total. After institution of the "two-field system," whereby grain rations became the responsibility of commune members themselves rather than of the collective as in the past, and the former wide plantings with thin harvests changed to intensive farming, the collective was then free to concentrate manpower, material and financial resources on development of economic diversification. Second, it was advantageous for agricultural production and for development of industrial sideline occupations. The fixing of output quotas on a household basis, or a large number of people being assigned responsibilities on a large scale has shackled people to the land and can hurt industrial sideline occupation production. In 1980, a year of major drought, grain output of many communes and brigades exceeded all-time highs, but earnings dropped. The "two-fields system" can solve this problem rather well. Since commodity fields are contracted for only by those engaged in agriculture, increases in agricultural output can be assured. On the other hand, since industrial sideline occupation personnel contract for grain ration fields and do not contract for or contract for only a little commodity fields, they are not held back by the commodity fields and are able to concentrate their energies on development of industrial sideline production. Third, the system helps the collective grow strong and helps the individual economy develop. A look at Qing County, which put the "two-field system" into practice, shows that grain ration fields plus private plots amount to about 30 percent of total cultivated land, which allows ample scope for the exercise of individual enthusiasm, and makes self-sufficiency or an excess entirely possible. The collective commodity fields, which account for about 70 percent of cultivated land, showed, on the one hand, an increase in commodity production and an increase in collective earnings because of the centralization of forces. On the other hand, with implementation of a responsibility system linked to output, the production efficiency rate steadily increased and costs steadily dropped, while at the same time a large amount of surplus labor could run workshops, do processing, vigorously develop industrial sideline production to change the situation of having nothing to sell but raw materials, thereby further developing and strengthening the collective economy. Fourth it helped the specialized division of labor, each person giving according to ability, gradually moving toward the specialization and socialization of production. In places that have instituted the "two-field system," though forms of responsibility systems linked to output are of many different kinds for commodity fields, they share a common point, namely the emphasis on workforce contracting on the basis of abilities. Those good at farming contract for land, and those good at other specialized trades to specialized contracting in farming, forestry, animal husbandry, sideline occupations, fisheries, or other service trades. Once the problem of grain rations has been solved, matters may be arranged on the basis of specialized division of labor. Consequently, practice of the "two-field system" helps unified administration by production teams and militates against a tendency toward "smallness but completeness in production on dispersed land. It helps the transition to and development of specialized and socialized production.

Institution of the "Two-Fields System" Requires Attention to Solution of the Following Several Problems. 1. The leaders' main energies must be focused on the commodity fields. Practice has shown that the "grain ration fields" can be easily started and commune members are also able to farm them well. The key to how well the "two-field system" will work lies in the "commodity fields." If there is laxness in the organization and leadership of the "commodity fields," possibly commune members will be concerned only about the "grain ration fields." The key to a good job in the "commodity fields" lies in implementation of various responsibility systems linked to output so that every member of the workforce involved in agricultural production will genuinely directly link how well the "commodity fields" are farmed to his own personal welfare. 2. The amount of "grain ration fields" has to be just right. In distributing "grain ration fields," the production from each field has to be estimated, the stardard used being ability to satisfy fields" take too much of the land, the collective economy will be hurt and those who have to work a lot will complain. If too little, it will be impossible to satisfy grain ration needs and those who do not have enough to do will complain. Any artificially created numerous and overeleborate intermediate links will also not find ready acceptance by the broad masses of people and cadres. In 1980, because "grain ration fields" were too few, individual production teams further apportioned grain from the commodity grain fields. As a result, both cadres and masses disliked the bother and

gave up the "two-field system." This is a lesson that should be remembered.
3. Once there are "grain ration fields," there is no further expansion of private plots. The situation in Qing County showed that earnings from "grain ration fields" were greater than from expansion of the number of private plots, and they were better able to satisfy the needs of the masses; consequently, the broad masses of cadres and people said that so long as "grain ration fields" endure for a long time, they would prefer "grain ration fields."

PERFORMANCE, PROSPECTS FOR SOYBEAN PRODUCTION PROVIDED

Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 2, 1982 pp 20-22

[Article by Yang Rongqiu [2799 2837 4428], Economic Research Institute, Heilongjiang Provincial State Farm Administration: "Taking Further Advantage of Heilongjiang Reclamation Area Soybean Production"]

[Text] China is called the motherland of soybeans, and Heilongjiang Province is renowned as the land of soybeans. After more than 30 years of development and construction, the Heilongjiang reclamation area has become a major national commodity base. The soybeans it produces are crucial to both Heilongjiang and to the country as a whole. Taking further advantage of Heilongjiang Province's reclamation area soybean production will not only advance all around development of reclamation area agriculture and increase reclamation area economic benefits, but will also have major significance for development of the national economy.

In 1950, the Heilongjiang Province state farm system's soybean output totaled 29 million jin. In 1980, it reached 1.57 billion jin, accounting for about 35 percent of the province's total soybean output for the year, and amounting to 11 percent of national soybean output for the year. During the 30 year period, the reclamation area's annual soybean output increased more than 50-fold for an accumulated output of 17.5 billion jin of soybeans, providing the country almost 8 billion jin of soybeans. In terms of output increase, development was rapid and the contribution to the country was by no means small.

The increase in soybean output is entirely attributable to the two factors of increase in growing area and yields per unit of area. Between 1950 and 1980, the area sown to soybeans in the reclamation area rose from 250,000 mu to 9.4 million mu, a 36-fold increase. Consequently, it may be supposed that the Heilongjiang reclamation area's 30 year increase in soybean output was primarily the result of a combination of expansion of cultivated area and corresponding expansion of the soybean growing area. The proportion of the reclamation area's total cultivated area sown to soybeans stood at 34 percent in the 1950's, and 32.4 percent in the 1960's, which means it was virtually steady.

Looked at in terms of output per unit of area, the reclamation area's soybean yields per unit of area averaged 116 jin in 1950 and 168 jin in 1980, a 45 percent increase in a period of 30 years. During the 1950's, the reclamation area's grain yields averaged 149 jin per mu, and in the first year of the 1980's, i.e. in 1980, they averaged 280 jin, an increase of 85 percent, much faster than the speed of increase of soybean yields per unit of area.

Soybean output as a ratio of total grain and soybean output has declined year by year. In the 1950's, it was 27.9 percent; in the 1960's, it was 26.1 percent; and in the 1970's it fell further to 23.6 percent. In comparison with the reclamation area's wheat and corn crops as well as in terms of the rate of increase per unit of area of soybeans, the level of development of soybean production has been slow.

2. Reasons For Slow Development of Reclamation Area Soybean Production

In the 30 years in which the Heilongjiang reclamation area has been in existence, why is it that the level of soybean production has not seen the same balanced development as grain production? The principal reason lies in the guiding mentality of agricultural production that considered soybeans to be a kind of grain, and which stressed "taking grain as the key link," and one-sidedly sought high standards of average output per unit of area. However, soybean yields per unit of area can scarcely attain the level of grain crops in general, so people regarded it as a "low yield crop." In an effort to "achieve the targets" [set in the National Agricultural Development Program] and to "exceed the target set for the region north of the Yellow River," some production units had no choice but to give priority to the use of material and technical forces on grain crops. They "emphasized grain and slighted soybeans," and they "emphasized wheat and slighted soybeans." In planning crops, priority went to planning of grain crops, soybeans being treated as an "afterthought." When it came to fertilization, soybeans got the "leavings." In cultivation and care too, soybeans "had to make way." Virtually everywhere soybeans were continuously cropped or yingcha [6601 9173] on the same land causing depletion of nutrients, a steady accumulation of toxic substances, and increasingly severe associated diseases, insect pests, and weeds, which hurt the formation of soybean root nodules leading to reduced yields. According to a 1980 survey, the area repeatedly cropped or yingcha to soybeans in the reclamation area amounted to more than 1.8 million mu or 19.6 percent of the total area sown to soybeans. The continuously cropped or yingcha area in individual units amounted to more than 40 percent of the total area sown.

In addition, some people felt soybeans had a low economic value and were not worthwhile growing. The price scissors between industrial and agricultural products in China is fairly great, and as grain crops go, the value of soybeans tends to be lower than that of cereal crops. According to statistics from a production team on Youyi Farm, in the 2 years since readjustment of the prices of agricultural products, the production teams' profits from growing wheat have been much higher than from soybeans. Price policies like this that favor wheat and discriminate against soybeans are another important reason why production of wheat has been emphasized and soybeans slighted, and why soybean production has developed slowly.

3. The Reclamation Area Possesses Tremendous Advantages For Development of Soybean Production

The Heilongjiang reclamation area's farms are distributed everywhere throughout the province. Those located in the high latitude zone between 45 and 50 degrees north latitude have a frost-free period of from 100 to 130 days, which is an arctic or sub-arctic climate. During July, temperatures reach a maximum of 30° to 35°C, and at night they range from 18° to 20°C. Rainfall is fairly adequate. As a result, daytime photosynthesis is vigorous and creates large quantities of nutrients. Here the soil is fertile and heat resources abundant. During the April to September soybean growing season, each square meter has 70.8 kilocalories of heat, and during the same period daily sunshine amounts to between 1,300 and 1,400 hours, higher than in China's other soybean producing areas of Shandong, Hebei, and Henan.

As a result of more than 30 years development and construction, abundant experiences have been accumulated about the tremendous advantages Heilongjiang's reclamation area offers for development of soybean production. This area possesses material and technical advantages that surpass those of other areas, including a fairly skilled agro-technical and farm machinery corps. The reclamation area's state farms are concentrated largely on the Sanjiang Plain and the Songnen Plain where the land area is extensive, the cultivated land is in continuous tracts, the lay of the land flat, and where a certain foundation of capital construction for agricultural use already exists. It is an ideal area for mechanized farming such as is rare elsewhere in the country. As a result, soybean production in the Heilongjiang reclamation area is extremely concentrated; quality is good; fat content is fairly high; color and luster are good; individual beans are even in size, and they are plump. They enjoy a high reputation not only within China, but are also highly competitive in international markets.

4. Taking Further Advantage of Heilongjiang Reclamation Area's Soybean Production

How to more fully make use of Heilongjiang reclamation area's advantages for soybean production requires that a good job be done in the following several respects.

First, appropriate readjustments have to be made in economic policies. Grain and soybeans should not be lumped together, but rather soybeans should be considered in a separate category. In terms of the overall development of agriculture, there should be a "big grain" concept, but just as peanuts, vegetables, sugar crops, and fruits are not included among grain crops, soybeans should likewise be separated out and returned to the economic crop category in which they formerly were. They should have their own requisition procurement quotas, and higher prices should be paid for production in excess of procurement quotas so that development of soybean production will rest on a necessary value foundation. Further study must be done on soybean procurement prices. In 1980, the price paid throughout reclamation areas for wheat and soybean sales to the state averaged 0.18 and 0.23 yuan per jin, which did not truly reflect the value of the soybeans. In international markets, the price ratio between wheat and soybeans mostly held at around 1:2, demonstrating that the position of soybeans in international markets also objectively reflected supply and demand relationships and their utility per se. This is something that merits our consideration. In short, there is need for readjustment of economic policies on soybeans so that economic benefits derived from the growing of soybeans will be no lower than for the growing of wheat or other cereal crops in order to stimulate enthusiasm on the part of production units for development of soybean production.

Second, Make Increases in Yields Per Unit of Area a Major Means For Developing Soybean Production

Within Heilongjiang's reclamation area, natural conditions differ scarcely at all from one farm to another, yet output shows great disparity. In 1980, soybean yields for the reclamation area averaged 168 jin per mu, while in 2 of 9 farm management bureaus, yields averaged only slightly more than 130 jin per mu, and for 10 farms with an area of almost 300,000 mu, soybean yields were less than 100 jin. Meanwhile, in the same year on an area of almost 100,000 mu at the Shanhe Farm located in the northwestern part of the reclamation area at 49°15' north latitude, soybean yields averaged 217 jin per mu, and on 22,500 mu, yields averaged more than 300 jin per mu. At the Tieli Farm in the southern foothills of Little Xing'an Range, yields from 57,000 mu of soybeans averaged 254 jin per mu. Statistical data also show that for the 4 years, 1965, 1966, 1975, and 1976, the Bawusan Farm annually planted more than 100,000 mu of soybeans from which it harvested yields averaging more than 260 jin per mu. From 1.3 million mu of soybeans planted in 1978 by the Mudanjiang Management Bureau, yields averaged 250 jin per mu. This shows that potential is still very great for increases in soybean yields per unit of area in the reclamation area. Therefore, increasing yields per unit of area should be the current main direction of attack in soybean production. Were soybean yields per unit of area to be increased to 200 jin during the next 2 or 3 years throughout the reclamation area, this would be an increase in output of more than 300 million jin.

Third is adoption of diverse measures to increase the overall soybean utilization rate. First, it is necessary to improve soybean processing technology. Soybeans are valuable for many different uses, yet we follow substantially traditional processing methods that produce a very low utilization rate. For example, most of the soybean oil used by workers and families throughout the reclamation area comes from processing done right on the farms within the reclamation area, but technology still consists of old style crushing methods that have an oil production rate of only 10 to 12 percent and, in some places, as low as 8 percent. Today, in many places inside and outside China, chemical solvents that have a recovery rate of more than 16 percent are used to recover soybean oil. If specialists were organized to develop and spread this technique, just within the reclamation area itself, requirements for soybeans could be reduced by 80 million jin. The pulp remaining after recovery of oil contains extremely abundant protein, which was formerly always used to make livestock feed and fertilizer in a very uneconomical way of doing things. Were already developed new technology to be used to make high quality foodstuffs such as fat-free bean flour, concentrated soybean protein, and artificial meat, milk, egg products, and water-free beancurd, as well as other bean manufactures to augment China's shortage of animal proteins, the products would not only have higher nutrition than animal protein, particularly nutritional value for health care, but would also increase economic benefits from soybean production.

The stalks, leaves, and pods of soybeans have always been regarded as a fuel to be burned by the people. However, soybean plant stalks contain more nutrients than any cereal grain. Measurements show that dried bean stalks contain about 2 percent total nitrogen, about 11 percent crude protein, about 9 percent other nitrogenous material, about 4 percent fat, as well as carbohydrates and various minerals. Were it possible to use a portion of the bean stalks plus some other raw materials to develop a livestock feed industry to manufacture full value feeds in order to promote development of a reclamation area livestock industry, the economic value would be very sizable.

Within the reclamation area, it is also necessary to intensify care of soybeans to do everything possible to increase the commodity rate for soybeans. In 1980, the Heilongjiang reclamation area produced 1.57 billion jin of soybeans, selling 880 million jin as commodity soybeans to the state for a commodity rate of 56 percent. Soybeans consumed within the area as seeds for livestock feed amounted to about 700 million jin. In fact, a certain amount of reduction in the "three retentions" for soybeans within the area is entirely possible. For example, vigorous extension of precision planting could bring about a drop in quantity of soybean seeds sown. By increasing the overall utilization rate of soybeans, without any drop in consumption as food for staff and workers or for livestock, consumption of soybeans could be reduced. Full use could be made of broken beans and small beans to reduce loss and waste, etc. If the "three retentions" of soybeans were reduced throughout the reclamation area by 10 percent, that would mean 70 million jin could be sent to markets, and from this source alone the reclamation area could increase earnings by from 20 to 30 million yuan, which would be very beneficial for the country, for enterprises, and for staff and workers.

BRIEFS

SUGAR PRODUCTION--In the 1981-1982 sugar producing period ending 15 May, Heilongjiang Province produced 365,000 tons of sugar, an increase of 49,000 tons over the previous sugar producing period. Profits from sugar production were 10 million yuan. The previous sugar producing period had losses of 4 million yuan. BRIEFS

SUMMER HARVEST CONFERENCE--The Hubei provincial conference on the summer harvest concluded on 28 May. The conference demanded that in the work of the summer harvest and preliminary distribution, all places lay stress on the examination and fulfillment of economic contracts. This year, rural areas in the province have universally implemented the agricultural production responsibility system and 91.8 percent of production teams throughout the province have signed economic contracts linking remuneration to output. As there are many forms of the responsibility system, there are many forms of the method of distribution. The contents of distribution and the method of work are greatly different from those in the past. Therefore, the key to doing well in preliminary distribution this year lies in examining and fulfilling the contracts. In accordance with the provisions in the contracts, we must settle accounts and put up notices of these accounts. We must seriously examine the situation of settling accounts, analyze the results in production, solve the existing problems and strengthen guidance in future production. Provincial CCP committee secretary Huang Zhizhen and vice governor Wang Hanzhang attended the conference and spoke. [HK010427 Wuhan Hubei Provincial Service in Mandarin 1100 GMT 29 May 82 HK]

BRIEFS

DROUGHT REPORT--Since the beginning of May, drought has threatened the growth of seedlings in paddy rice fields in Shuangyang and Yongji counties in Jilin Province. Over 73,000 people and 2,800 vehicles are out every day to deliver water and replant seedlings of paddy rice fields in Shuangyang County. As of 23 May, this county had replanted some 150,000 mu of paddy rice fields. Some 30,000 mu of paddy rice fields are seriously hit by drought in Yongji County. RECOMMENDATIONS FOR MORE COMMODITIES FOR RURAL PEOPLE

SK260400 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 25 May 82

[Text] Since the third plenary session, the peasants have become prosperous. One of the important manifestations of this is the increase in their purchasing power. However, during the January-April period of 1982, varieties of commodities in rural supply and marketing cooperatives in the province decreased by several hundred compared with the previous situation. Many commodities were out of stock, and the peasants were dissatisfied. During this period, over 1,000 industrial and commercial goods valued at 1.6 to 1.7 billion yuan were stockpiled, affecting the circulation of funds and resulting in a decrease in state revenue. This situation must be changed. However, some cadres contend it is difficult to organize industrial goods for rural areas because our province lacks popular brand products and high-grade goods. This argument is untenable.

Through investigations, we have realized that in many rural supply and marketing cooperatives, commodities are in short supply, product varieties are inadequate and many daily necessities are out of stock. Some peasants said they even have difficulty buying quilts and quilt covers, not to mention washing machines. True, popular brand products and high-grade goods are welcomed by the peasants; however, this only accounts for a small proportion of commodities orientation.

Haicheng County commercial departments have opened up all channels and tried every means to deliver industrial goods to rural areas. Since the beginning of this year, the sales volume of commodities in this county has increased 20 percent over the corresponding 1981 period. The peasants are satisfied with this. This has increased the revenue of the state. Experience shows that solving the problems of deficient market supplies in rural areas and overstocking of commercial goods is not just a general acknowledgement of serving the peasants and the rural markets on the part of commercial departments. Efforts must be made to adopt all kinds of feasible methods to realize the peasants' needs, to investigate and study the rural market trends and to deliver industrial goods to the rural areas in a prompt and timely manner.

NEI MONGGOL

BRIEFS

SPRING FARMING--Bayan Nuir League of Nei Monggol Region has completed sowing main crops in accordance with the state plan. By mid-May, the league had sown 3.92 million mu of wheat, corn, Chinese sorghum and sugar beets. [SK271155 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 26 May 82 SK]

WEATHER FORECAST--According to the forecast by the Nei Monggol Regional Meteorological Observatory, from June to August the precipitation in most areas of the region will be less than usual. Hulun Buir League, Western Alxa League and northern Xilin Gol League will probably be stricken by a sustained drought. Various leagues and municipalities in the west and central parts of the region will have dry weather from June until late summer. After the beginning of August, signs of drought will be alleviated. Ulanqab and Bayannur leagues will probably be hit by flooding and waterlogging. From June to August, temperatures in most areas of the region will be similar to that of past years. FARM, LAND RECLAMATION CONFERENCE CONCLUDES

SK210540 Xining Qinghai Provincial Service in Mandarin 1100 GMT 20 May 82

[Text] According to our sources, the provincial farm and land reclamation work conference jointly sponsored by the provincial agriculture and forestry department and the provincial finance department concluded on 17 May in Xining after a 10-day session. The conference emphatically discussed specific methods for state farms and livestock farms on improving management, raising economic results and making a breakthrough in farm and land reclamation economy.

Attending the conference were responsible comrades of various farms and livestock farms on the provincial farm and land reclamation front and responsible comrades of various prefectures, municipalities and counties. Speaking at the conference were the provincial party and government leading comrades including Ga-bu-long, Xu Linfeng, Wang Fuxiang and (Liu Fengjia).

Farm and land reclamation departments throughout the province achieved a total of 17 million yuan of output value last year and provided a fairly great amount of grain, oil and sideline products for the state. Their losses also decreased somewhat. However, only one-third of them showed a profit. The task of converting deficits into profits is still very arduous.

As for the issue of making a breakthrough in developing our province's farm and land reclamation projects, Comrade (Liu Fengjia) said in his summing up speech: In developing the state farms and livestock farms, it is necessary to uphold the principle of developing diversified forms of economy, with stress on one of them and persist in making agriculture, industry and commerce a coordinated process to develop them in an all-round way. Facts have shown that farm and land reclamation enterprises will not be stable without agriculture and animal husbandry will not be prosperous without industry and will not be enlivened without commerce. Therefore, it is an effective method to make agriculture, industry and commerce a coordinated process in order to develop them comprehensively.

State farms and livestock farms throughout the province should encourage the whole people-run units, collectives and individuals to develop a diversified economy through concerted efforts and vigorously prepare the ground for changing farm and land reclamation enterprises to integrated complexes of agriculture, industry and commerce. It is also necessary to institute the subsistence system in monetary affairs to promote the work of converting deficits to profits. The subsistence system in monetary affairs should be aimed at independent accounting, assuming sole responsibility for profits or losses, retaining the surplus and making up the losses through its own efforts. The enterprises which have not instituted the subsistence system must institute it conscientiously. At the same time, the responsibility system in production should be improved and implemented so as to integrate the economic interest of workers and staff with the economic results of enterprises. Various farms and livestock farms should sum up and implement the above-mentioned systems and make great efforts to improve them.

BRIEFS

XINING SPRING AFFORESTATION--Qinghai Province has basically completed spring afforestation work. As of mid-May, over 1 million people throughout the province participated in tree-planting work. They afforested 90,000 mu of land in urban areas, planted 19.3 million trees around villages and houses and along canals and roads and grew 35,000 mu of saplings, fulfilling the annual plans by over 72 percent. In addition, Haibei, Hainan and Haixi prefectures, Huangnan Tibetan Autonomous Prefecture and Hualong Hui Autonomous County have overfulfilled the annual afforestation tasks. [SK301046 Xining Qinghai Provincial Service in Mandarin 2330 GMT 27 May 82 SK]

WATER QUALITY IMPROVED--In the past 3 years, Qinghai Province has built and reconstructed 106 projects to improve the quality of potable water in areas where people are plagued by fluorine poisoning and goiter. The incidents of such diseases have begun to decline. [SK271200 Xining Qinghai Provincial Service in Mandarin 2330 GMT 26 May 82 SK]

METHODS TO ACHIEVE SELF-SUFFICIENCY IN EDIBLE OIL OUTLINED

Xian SHAANXI RIBAO in Chinese 7 Mar 82 p 2

[Article by Fan Guoxin [5400 0948 2450], Provincial Agricultural Bureau: "Seize the Opportunity To Plant Oil-Bearing Crops Well and in Sufficient Amounts"]

[Text] During the past several years Shaanxi Province's development of oil-bearing crops has been rapid. Since last year, in particular, after the provincial CCP Committee and provincial government proposed an equitable readjustment of crop patterns with increased growing of oil-bearing crops as a measure for achieving self-sufficiency in edible oil in the province, production of oil-bearing crops has been further promoted, and oil-bearing crop yields per unit of area, total output, and quantities of oil purchased have all exceeded the all-time high records. In a single year the onus of importing oil from other provinces has been removed, and the province has become substantially self-sufficient in edible oil.

As a result of last fall's continuously overcast and rainy weather, however, completion of fall rape sowing tasks was somewhat faulty, and the area planted declined by more than 300,000 mu over the previous year. In addition, as a result of frosts and freezes, low temperature, and inadequate sunshine, growth of rape seedlings was slow, and the condition of seedlings this year is the worst it has been for the past several years. Despite the meticulous and solid care given rape before the onset of winter in 1981, because of the fairly great reduction in the area planted to rape, inevitably total output must be affected. Therefore, all jurisdictions should follow the principle of "spring sowing to make up for inadequate fall sowing; minor oil-bearing crops to make up for a reduction in rape; and oil must be grown if it is to be eaten." Simultaneous with good field care of rape during the spring season, every available means should be used to fulfill sowing plans for oil-bearing crops to assure self-sufficiency in edible oil for local regions. Minor oil-bearing crops are characterized by numerous kinds and strong adaptability. Examples are northern Shaanxi's dwarf jute, [1420 7802 1311] [as published] linseed, and spring rape, the peanuts, sesame, and perilla of central and southern Shaanxi, and the castor and sunflowers that lend themselves to growing in all parts of the province. Mountain regions, plains, and hill regions having the conditions can adapt general methods to local situations to make appropriate plantings. The masses may also be stirred to make full use of idle land, saline-alkaline wastelands, places in front of and behind their homes, and the 10 besides [odd bits of land in various places] for large scale growing of minor oil-bearing crops.

In order to change the low yields obtained from oil-bearing crops, farming techniques must make new breakthroughs. Jobs such as selection of fine varieties, planting at the right times, planting in the proper density, field care, careful leveling of the land, and increased fertilization must be done conscientiously. Minor oil-bearing crops cannot be treated like some incidental farm work, but care must be taken in planting and in harvesting for bumper output and bumper earnings to improve the level of Shaanxi Province's self-sufficiency in edible oil over the years.

MOBILIZATION CALL TO BEGIN SPRING PLANTING ISSUED

Xian SHAANXI RIBAO in Chinese 3 Mar 82 pp 1, 2

[Article by Yu Mingtao [0060 2494 3447]: "Urgently Mobilize to Bring About a Rapid Upsurge in Spring Production. Speech Made in a Provincial CCP Committee and Provincial Government Telephone Conference to Mobilize For Spring Production"]

[Text] Comrades:

On the basis of decisions made by the Provincial CCP Committee and the provincial government, this evening's telephone conference is principally for the purpose of preparing further action on the issue of spring production.

The overall situation in rural villages throughout the province is currently good. Right after the lunar new year, all counties and municipalities held three or four work conferences, one after another, in the spirit of both this year's Central Committee document No 1 and the Provincial CCP Committee's January work conference to take multiple action on rural work. Right now, consolidation and perfection of production responsibility systems, reorganization of grassroots leadership bodies, solving problems of unhealthy tendencies in the "three attracts, three changes, and one steady," attacks against criminal economic activities such as engaging in speculation and profiteering, smuggling and trafficking, and arranging for the livelihood of people in disaster areas is gradually being done in an orderly way. The spring production situation in rural villages throughout the province is also good. Enthusiasm of cadres and the masses is fairly high; many places have strengthened leadership of spring production, have trained and sent to rural villages large numbers of cadres to provide guidance and to solve problems face to face on the ground. Scientific and technical personnel and old peasants have been organized to inspect, plot by plot, the summer field growth situation and to provide tailored guidance in suggestions and measures. Some places have organized all levels of cadres for large scale planting of experimental fields and to explore experiences in increasing yields of all categories of crops. Many places have leveled fields and fertilized, have done spring hoeing, spring plowing, spring irrigation, afforestation, and various production activities. The most conspicuous problems existing at the present time are insufficient stress placed on this central matter of spring farming and production in very many places resulting from the substantial number of work tasks and the dispersal of leadership strength; a fragmented rural grassroots organization lacking in strength in may places, with some cadres washing their hands of involvement with present production; and the substantial shortage of means of production such as chemical fertilizer, plastic sheeting, farm machines and equipment, and wooden and bamboo implements needed in spring farming, transportation and supply of which has not been done on time. Meriting particular attention is that numerous leadership comrades seriously lack perception of these problems, do not take sufficiently vigorous measures to solve them, or even let things drift along on their own course without doing anything about them. These things are all extremely bad for doing a good job of spring production.

The central task of the moment at all levels of CCP committees and government in rural villages is to concentrate forces, strengthen leadership, and urgently mobilize, and through reliance on policies and science to bring about a rapid upsurge in spring production. To this end, and in the spirit of discussions by the Standing Committee of the Provincial CCP Committee, the following several problems are to be emphasized.

First Is Use of Every Possible Means to Win a Bumper Summer Harvest

Failure to win a bumper summer harvest will be a major matter affecting the situation as a whole. Summer grain has accounted for more than 40 percent of the Province's total grain output. A high commodity rate has extremely great ramifications in arranging for the people's livelihood in cities and countryside and for market supply. Since the founding of the People's Republic, 6 years have brought great bumper summer harvests, which meant not only a good agricultural life for the years concerned, but also a winning of the initiative for work in industry, culture and education, finance and trade. Conversely, if summer grain harvests are scanty, nobody's life is good. Therefore, we must keep our eyes on the situation as a whole, devoting attention first of all to this year's summer grain production, then going on take in hand grain production for the entire year in order to advance development of agriculture as a whole and the national economy of the province.

In order to win a bumper summer harvest, the Provincial CCP Committee and provincial government convened a provincewide agricultural work conference in November 1981 at which it made concrete arrangements, and at which all jurisdictions did a great amount of work, as a result of which definite achievements have been made. However, we must realize that as a result of the long periods of rainy, overcast weather last year, a substantial portion of the wheat was planted late and planted carelessly. November, the month in which wheat tillers vigorously, had somewhat low temperatures, and accumulated temperatures were more than 100 degrees less than in most years. Wheatfield's had generally between 40,000 and 50,000 fewer seedlings per mu than in most years, and one or two fewer tillers per plant. Moreover, the overwintering seedling situation has been generally poorer than during the previous year, slipping by about one grade. That is to say that this year's first grade seedlings would be classed as second grade seedlings in previous years. Since the lunar new year, the weather has continued abnormal. For more than 40 days there have been virtually no clear skies and sunshine has been inadequate, yet very little rain has fallen. Though rain or snow has fallen several times, it did not amount to anything substantial, and though basic soil moisture is good, moisture in the soil's surface horizon is inadequate. Right now some areas to the north of the Wei are experiencing drought, the drought area covering about 7 million mu. A survey done during the first 10 days of February in Puchen County shows soil water content to be only about 10 percent. The national meteorological forecast calls for continued low rain and snowfall in many areas this spring, and during May and June a "return to spring coldness" may occur, which would be damaging to wheat and rape growth and development. A problem exists in that some of our comrades have yet to give sufficient attention to these circumstances. Some are blindly optimistic supposing that since the soil moisture situation at the end of last year was good, since the wheat growing area is large, and since a lot of wheat is now growing, the problem of a bumper harvest is not a big one. Some passively complain about hardships, supposing that since the basic seedling situation is poor, better care will not make any difference. Some just drift along, supposing that with the implementation of production responsibility systems, it is the peasants themselves who should do the worrying and that there is no use in higher authority being much concerned, with the result that they slacken field care. We have to educate cadres and masses to realize the favorable conditions for production from the summer fields, and realize even more the disadvantageous factors so that the point on which they base themselves and the focus of their work will be the adoption of effective measures to triumph over hardships to promote an upward transformation in the summer fields. Only in this way can a bumper harvest be assured. Right now we are a little more than 3 months away from the summer harvest, and there is a very great amount of room for maneuver in field care. If only we concentrate our strength and do everything possible during these next 3 or 4 crucial months, the winning of a bumper harvest shows great hope. The next 3 or 4 months are a crucial period for the end of tillering, increase in number of spikes, and increase in number of grains of wheat. If work is done well during this stage, a turn around in the seedling situation can be brought about very quickly in a change from the passive to the active. Beginning now, all jurisdictions should concentrate their manpower and material resources to make a ferocious effort in field care.

First attention should go to balanced increases in output. Both wetlands and drylands should be given attention at the same time. In the wetlands a campaign for 10 percent increase in grain should be launched. If the province's wetlands yield an average 400 to 500 jin of wheat per mu, between 4 and 5 billion jin can be taken from 10 million mu. For drylands, the focus should be on the dryland plain area north of the Wei. This region accounts for about 30 percent of the province's total output of wheat. If this region has a bumper output, the province as a whole will have a bumper harvest. We must base ourselves on preventing and combating drought, take conscientious measures, cultivate the fields to preserve soil moisture, increase fertilization, prevent and control diseases and insect pests, and strive for wide area balanced increased in output.

Second is attention to crucial measures. The Provincial CCP Committee and provincial government have transmitted the minutes and specific measures of a symposium of wheat and rape specialists in Shaanxi Province on this issue, so there is no need for detailed discussion of methods. The emphasis should go on attention to fertilizer and water problems.

Fertilizer is food for crops. Success or failure in winning a bumper harvest this year will be determined to a very large extent by the quantity of fertilizer that is spread. To the maximum extent possible, existing chemical fertilizer should be used on places watered by rivers in an effort to get yields of between 30 and 40 jin per mu. In order to compensate for the current shortage of chemical fertilizer, supply and marketing units can draw down to the lowest possible extent the revolving chemical fertilizer maintained in storage for maximum use in spring production. In addition, general methods should be adapted to specific situations to launch mass campaigns of looking for fertilizer and accumulating fertilizer, and strenuous attention given to the raising of livestock to accumulate manure. Good management of human and livestock wastes should be done. As part of the patriotic sanitation campaign, garbage should be cleaned up, and city feces collected to be sent to the countryside to provide quick acting fertilizer for the wheatfields, and to make ready sufficient base fertilizer for spring sowing.

Water conservancy is the life blood of agriculture. Capital construction of farmland water conservancy should be closely related to spring production, with attention given to tapping the potential, fully equipping and finishing up water conservancy projects. A 3 million mu area in the province has not yet been fully equipped, so action should be taken on this area with all possible speed to make the most of irrigation benefits. The potential from fully equipping the Fengjiashan and the Donglei projects is very great. If conscientious attention is directed to these projects, an irrigated area of more than 200,000 mu can be added this year. The pace of spring irrigation should be particularly hastened. Only 2 million mu of the planned 10.3 million mu planned for spring irrigation in the province has so far been irrigated. All jurisdictions should clarify reasons for the slow pace of irrigation, and solve both problems in understanding and genuine problems of insufficient irrigation funds, poor maintenance of equipment and facilities, and poor management of irrigation. They should vigorously improve irrigation techniques, actively promote good experiences in pooling the flow of people's wells, reviving old wells, and extending irrigation ditches, and make fullest use of the role of various kinds of power machines and water lifting equipment. Return to the fields of every drop of water is to be advocated, and the irrigated area enlarged to the maximum possible extent so that limited amounts of water bring maximum results. Strenuous efforts should be made on the dryland plain to the north of the Wei to store water and conserve soil moisture with vigorous launching of mass building of storage ponds, pools, and some small scale water storage projects, both to solve the problem of drinking water for people and livestock and to provide water sources for the planting of potatoes and multiple crops of corn to reduce losses caused by the drought.

Second Is Diligently Doing a Good Job of Spring Sowing

Most important in spring sowing is attention to the sowing of early fall ripening crops and economic crops such as cotton and spring oil-bearing crops. Last fall's reduced production of grain and cotton as a result of disasters created great losses for us. This year, it is necessary to make up our minds to increase the harvest from autumn crops. Right now, most important is preparations to plant them to assure that enough are planted and that they are planted well. First, the planting area should be designated according to plan. For the past 2 years, we have followed the principle of adapting general methods to local situations as regards the growing area for cotton, oil-bearing crops, and other economic crops, making appropriate readjustments so that the crop pattern has gradually become equitable, and results have begun to show. Now crop patterns throughout the province should be stabilized with no further readjustments being made. In view of the tendency of not planting according to plan that has occurred in some places, when making plans for spring sowing this year, stress should be placed on obedience to state plans, assuring the grain growing area first. For the present and a fairly long time in the future, grain production must take first place. Given the situation of large transport into the province of grain to eat, there can be no slackening of grain production. Inasmuch as cultivated land is limited in quantity, both for grain and the development of economic crops, most important is raising yields per unit of area and increasing total output. To the maximum extent possible, the growing of economic crops will have to be done on barren mountains and wasteland slopes; there can be no encroachment upon grain fields. This year a tendency toward blind development of the flue-cured tobacco area has occurred that merits close attention. Last year 140,000 mu of flue-cured tobacco was actually harvested throughout the province, and 310,000 dan was purchased by the state. This year's plans call for the sowing of 200,000 mu, but reportedly various places plan on planting a total of 320,000 mu, and an output of 750,000 dan is forecast, an amount vastly in excess of the province's annual requirement for from 300,000 to 400,000 dan. Unless promptly controlled, a situation of slack sales will occur, which will strike at the enthusiasm of the peasants in turn. It is hoped that every jurisdiction will plant the planned area and no more.

Cotton production should be placed on the important agenda of all levels of party and government leadership in cotton growing areas. Cotton is Shaanxi Province's, and particularly central Shaanxi Province's, most important economic crop, and has very great pertinence for the national economy and the people's livelihood. However, during the past several years output has fluctuated without making any progress. It has not been possible to increase it, and last year another disaster seriously reduced output, and damaged the masses' income and development of the cotton textile industry. We certainly must make up our minds to bring about an upswing in cotton production. First the cottonfield area has to be guaranteed. Planned cotton growing area for the province this year is 3.8 million mu, but according to reports from various places, only 3.7 million mu has been planted, a 100,000 mu shortfall. Now it is necessary to place responsibility level by level, and see to implementation county by county, commune by commune, and production brigade by production brigade. If the cottonfield area is inadequate, it should be augmented first from land intended to lay fallow, and if it is still inadequate, wheat fields and rape fields may be used for the transplanting of some seedlings. Second is the need to link implementation of grain policies with grain procurement, giving across-the-board consideration. Third is the need to combine preparations for farming with implementation of cottonfield production responsibility systems and the signing of economic contracts. Outputs must be equitably fixed, and a tendency to be high or low guarded against so that cotton growing peasants will be able to exceed planned production through effort, and have a profit to show for it. Fourth is solution to the problem of insufficient cotton seeds. This year cotton seeds are short in quantity and poor in quality. Experiments done in various places show a sprouting rate for the seeds generally around 40 to 50 percent. Right now the emphasis should be on seed selection, seed shipment, and transfers of surpluses to shortage areas. Sprouting tests should be run everywhere on available seeds, and a seed selection and seed sunning campaign should be begun to increase the sprouting rate, to prepare a sufficient number of cotton seeds, and to assure that the area to be sown will not be adversely affected by a lack of seeds. Fifth is the need to do a good job of technical training and to summarize and spread local advanced experiences, particularly experiences in increasing outputs during disaster years. Scientific cotton farming is to be advocated. Propagation of seedlings for transplanting is an effective means of increasing yields, so plastic sheeting and seedling beds should be promptly made ready. Sowing should be done before 20 March, and timing should not be off. Where conditions permit, certainly means should be figured out for planting more. Sixth is further strengthening of leadership of cotton production. In key cotton growing areas, organizations involved with cotton should be fully sound, should strengthen forces, and positively should not weaken them. Last year disasters reduced cotton output, so some of the masses and cadres lack adequate confidence in growing cotton. Their education must be intensified to overcome feelings of apathy, actively spreading the advanced experiences of other provinces and of Shaanxi Province in increasing outputs of cotton, and establishing confidence about being able to bring about an upswing in cotton production. The province has set 7 March as the date for a provincewide conference on cotton production, for an exchange of experiences, for a check on readiness for farming, and for implementation of cotton growing plans and measures for increasing output. It is hoped that following the conference, all jurisdictions will diligently implement the spirit of the conference, and devote attention to cotton production.

Simultaneous with attention of summer field care and spring sowing should be attention to spring mating and epidemic prevention among livestock, particularly serious attention going to the problem of reversing the decline in live hogs. Unless given a high degree of serious attention, this problem could very possibly result in no pork to eat during the last half of the year in a change from "selling hogs is hard" to "buying pork is hard." All jurisdictions should conscientiously carry out the provincial government's recently issued "Notice on Strengthening Live Hog Production and Management." They should intensify investigation and study, check and summarize the reasons for and the lessons to be learned from the drop in live hog production, and promptly help the masses with problems in production, supply, and marketing. They should protect and expand the growth of boars and sows to assure sources for hogs so that hog raising endeavors will be quickly revived and developed.

Third Is Doing a Genuinely Good Job of Material Supply for Spring Production

Enhancement of the supply of materials is a powerful guarantee for doing a good job of spring production. Acting under the guidance of all levels of CCP committees and government, all units concerned should take concerted action in energetic support of spring farming. The recent meeting of provincial units concerned, convened by the provincial government, specially studied the problems in this regard. First was the need to do a good job of chemical fertilizer production and supply. The present insufficient quantity and lack of needed kinds of chemical fertilizer is a conspicuous problem for agricultural production. The provincial government has decided that henceforth the chemical fertilizer produced within the province must be used on agricultural production in the province, with no marketing whatsoever permitted outside the province. Following centralized distribution plans of agricultural departments and centralized dealings by supply and marketing departments, all chemical fertilizer produced by chemical fertilizer companies will be sold exclusively by supply and marketing cooperatives. Sale price of chemical fertilizer will continue unchanged at the list price set by the state. The procurement price has been set jointly by the Provincial Planning Commission, the Petrochemical Bureau, and the Supply and Marketing Administration. Both the industrial and business sector are to diligently put this price into effect so that there will be no change in supply at near places or distant places resulting from price, causing hardships for the peasants. In addition, there should be resolute opposition to unhealthy tendencies in the supply and marketing of chemical fertilizer, and when problems are discovered they should be severely dealt with. Second is attention to production of plastic sheeting. It is now very close to the time when cotton seedlings are propagated, but the amount of plastic sheeting available is far from able to meet needs. It has been decided that light industrial units should concentrade their forces and concentrate raw materials in a night and day attack for priority production of an amount of plastic sheeting for farm use to catch up with seedling needs. Farm machinery and water conservancy units should organize small agricultural support teams to go to villages to help communes and brigades get their farm machinery and implements, and their pesticide apparatus in shape, as well as to repair and equip irrigation devices. Special attention should be given the energetic production and supply of the various small metal and wooden farm tools rural villages urgently need that are in keeping with establishment of production responsibility systems. Commercial and transportation units must be sure to transport to communes and brigades in time for the farming season the means of production needed for spring farming. In short, all trades and industries are to make a contribution to the support of spring farming and production.

All levels of CCP committee and government are to strengthen leadership, place spring farming and production in an important place, and conscientiously handle it as a central task. Integrated planning of various tasks should be done, and there should be no dissipation of energy and no shouldering aside of spring production. The work teams that the province has sent everywhere are to provide a certain force to help the local party and government leaders take spring production in hand. They are to help the masses solve genuine problems. All jurisdictions are to further diligently implement this year's Central Committee document No 1, and the spirit of the Provincial CCP Committee January Work Conference to eliminate various mental apprehensions existing among cadres and the masses. No matter the forms of production responsibility system practiced, they should be consolidated and further perfected with no further changes being made lightly, so that the masses will set their minds at ease and get on with spring farming and production. Cadre responsibility systems and technical promotion responsibility systems linked to output are to be established. Leaders at all levels are to take the lead in the planting of experimental fields, to explore experiences in increasing yields, and to guide work in the area as a whole. As a result of the planting of experimental fields, they should straighten out their ideological line, learn about science and technology, and gradually become both red and expert. Agricultural science and technical personnel should go into the fields to analyze plant situations and recommend specific care measures. Management of workforces should be improved with overall planning done for use of labor in agriculture, industry, and sideline occupations to prevent an outflow of workforces in order to assure workforce needs on the front line of spring farming and production. Reorganization of grassroots organizations is to be done, leadership groups for the reorganization at the grassroots acting to give impetus to current production. Consolidation and replenishment of grassroots cadre ranks, support to them to work courageously and lead production well is to be done. Management of markets is to be strengthened, and attacks directed against profiteering and speculation in the maintenance of order for spring production. Good planning for the livelihood of the masses is to be done, particularly attention being given to disaster areas here and there and to newly discovered disaster areas to guarantee a minimum standard of living for the disaster area masses and the necessary conditions for carrying on production. The Provincial CCP Committee and provincial government have issued a special notice about the issue of living arrangements, which should be put into effect at once to assure that no problems arise. Spiritual civilization and material civilization are to be linked, spiritual civilization giving impetus to the building of production. Good people who do good deeds are to be commended, and an emulation campaign should be launched to arouse the masses' enthusiasm for doing a good job of spring production, and to contribute their strength to winning a bumper summer grain harvest and an all around bumper harvest in agriculture for the year as a whole.

WESTERN MOUNTAIN REGION BLOSSOMS WITH AFFORESTATION

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 1, 5 Jan 82, pp 13-14

[Article by Correspondent Zhang Guoning [1728 0948 1380]: "The Hope in View from the Western Mountain Region"]

[Text] The western mountain region of Shanxi Province includes the 4 prefectures of Yanbei, Xinxian, Luliang and Linfen, plus the 32 counties and districts of Taiyuan and Datong. Since 1978, the pace of greening has greatly accelerated on the 51,000 square kilometers of land extending from the Great Wall in the north to the southern end of Luliang Mountain. As of 1981, the area that had been afforested and survived in the western mountain region amounted to 3.46 million mu. The wasteland hills and bald mountains and the countless ravines and valleys of Youyu, Yonghe, Ji and Xiangning counties were decked in green. This provided a model for control of the loess highlands and the building of the "Three Norths" shelter forest system.

Taking the Road of Forest and Livestock Development First

The western mountain region occupies one-third the total land area of Shanxi Province. Cultivated land amounts to 25.5 percent of the total in the province, but during the past several years grain output has amounted to only 16.1 percent of the province's total, and peasant earnings are low. It is the poorest place in Shanxi Province, every county and commune having a group of "three dependents" brigades. The food and clothing problems of the peasants have not yet been solved.

The western mountain region has been liberated for more than 30 years, so why have changes in its circumstances not been very great? Mostly for two reasons. One has been the excessive clearing of land and reckless timbering over a long period of time that has resulted in scant vegetation cover and serious erosion. As the masses say, "When mountains are cleared all the way to the top, people become poor and die out." Secondly, "leftist" humbug bound the peasants hand and foot so they were unable to adapt farming to the local land. Mountain areas should place the planting of trees, the growing of grass and water and soil conservation in a primary position; however, several years ago, great emphasis was given to "changing the soil to control water," removing mountains and filling in ravines and building reservoirs.

An overwhelming majority of places should have made forestry and animal husbandry foremost in the practice of economic diversification, but for a long time they practiced "monoculture." Programs to set things right were not on the track, and the damage done is difficult to measure. A survey done by provincial water conservancy departments shows that over the years a total of 110 large, medium and small reservoirs were built in the western mountains. Of the total, 298 million cubic meters or 34.6 percent of 11 large- and medium-size reservoirs with a storage capacity totaling 860 million cubic meters have silted up. This is to say that one-third of the reservoirs have been rendered useless. The masses sadly say, "We don't mind working hard, but we do mind working in vain!"

Following the 3d Plenary Session [of the 11th Party Central Committee], the Shanxi Provincial CCP Committee and the Shanxi Provincial People's Government conducted a diligent investigation and study of the western mountain region and decided that the western mountain region should unswervingly follow a course of making forestry and animal husbandry paramount. They took the following action: (1) Liberalized policies, using to maximum extent western mountain region advantages in having much land suitable for forests. Wasteland hills under state forest farm administration would be afforested jointly with communes and brigades, or else a portion of them would be designated for administration by neighboring communes and brigades. Commune and brigade barren hills suitable for forests, the large area afforestation of which could not be completed within a short period of time, would be partially turned over to state farms or groups for afforestation. Trees grown in front of and behind commune member houses that had been confiscated during the movement to learn from Dazhai were to be returned in toto. Those that had been cut down would be compensated with cash. (During the past more than 2 years, more than 1.6 million trees have been returned, and more than 250,000 yuan in restitution paid.) Destruction of forests and clearing of land have been strictly prohibited, and some counties have replanted forests and grass on cleared land with a slope of more than 25 degrees. They have also designated for the planting of trees by individual commune members wasteland hills, slopes and ravines suitable for the growing of forests. (2) Proper handling of the relationship between forests and grain. Except for those places having conditions requiring building of basic farmland to achieve self-sufficiency in grain, for the next few years in those counties where self-sufficiency in grain will be difficult to achieve, the requirement to achieve self-sufficiency in consumption grain rations should not be pushed. Instead, grain shortfalls should be solved on a case-by-case basis of area afforested and preserved. During the past 2 years, in addition to reducing and exempting excess grain procurement and some public grain procurement, the Provincial People's Government has allocated 170 million jin of grain to support western mountain region development of economic diversification. Once the masses had been relieved of the nagging worry of having food to eat, their enthusiasm for the planting of trees and the growing of grass redoubled. (3) Increased investment in forestry. In addition to the sums provided the western mountain region by the "Three Norths" Bureau, in recent years the Provincial People's Government managed to find an additional more than 7 million yuan of local public funds for support. More than 10 counties also collected somewhat more than 4.3 million yuan themselves for development of forestry. Some prosperous communes and brigades consciously applied public accumulation funds to afforestation. At the same time, counties signed agreements with communes and brigades for civilian cooperation and public assistance in afforestation. That set the tasks to be performed, the quality, the time period, the remuneration and the rewards and penalties. After the contracts were signed, 60 percent of the support funds were paid. Following strict examination prior to approval to assure that survival rate and conservation area requirements had been met, the remaining 40 percent was handed over. This way of doing things combined responsibilities, rights and benefits for very good results. (4) Intensification of care and protection of mountain forests to improve economic benefits. Following Provincial CCP Committee approval, the Shanxi Shelterforest Construction Bureau was established in 1979. This special management organization devoted itself to two principal tasks. The first was to help each of the counties to carry out a rectification of ideological style, consisting largely of education by positive measures or examples, at the more than 30 forestry stations. Second was to maintain a work focus directed mostly toward the four river basin tracts of the upper reaches of the Fen He, Songjia Chuan, Sanchuan He and Xinshui He, and at the windblown sand line running along the Great Wall, helping the prefectures and counties concerned to select, on the basis of the mountain system and stream basins, more than 80 key forestry projects. The minimum area suitable for forests in this project was somewhat more than 10,000 mu each. In 1981 alone, somewhat more than 100 provincial, prefecture, county and commune forestry sites afforested and kept alive more than 388,000 mu. Afforestation standards were high and quality good, serving as a model for individual communes and brigades, and providing zest for development of large area afforestation.

"Thirty percent afforestation and 70 percent care." Once afforestation had been done, administration and management was crucial. They used various forms of responsibility systems such as specialized contracting and linking output to calculation of remuneration to assure good care for forest trees. The form of a responsibility system practiced by Ji County was largely one of full contracting for propagation of seedlings, preparation of land, planting and protection over a several-year period. Workpoints were recorded each year for 85 percent of the specified amount of work, and following inspection and approval in the succeeding year, bonuses or penalties were awarded according to survival rates. Some places contracted individual jobs or multiple jobs, small work segments, or large-scale assignment of responsibilities. In order to solve the problem of no immediate material benefits from forest contracting, Ji County did four things. First, it designated certain land for use in growing both forests and grain as supplementary assistance to the contractors. Second, for brigades in which workpoints had a high value, bonus workpoints were equitably collectively given for farming, forestry, animal husbandry and sideline occupations. Third, grain or money allowances were given forestry personnel on the basis of their work. Fourth, a system of sole responsibility for profits and losses was instituted for production teams with orchards, excess output being theirs to keep. Institution of responsibility systems not only fully aroused the enthusiasm of the myriad households for afforestation, but also greatly increased the forest conservation rate and commodity rate.

Reliance on the power of policies greatly hastened the pace of the greening of the western mountains, which advanced at an annual rate averaging 860,000 mu. In some counties, afforestation averaged 1 mu per capita per year. In addition, more than 460,000 mu of pasture grass was planted, and 500,000 mu of mountains were closed off to the public for return to forests or grasslands. Each year more than 130,000 mu of seedlings were grown. For the past 4 years, the Xinshui He basin in Linfen Prefecture has annually afforested a preserve area of more than 300,000 mu for the initial formation of a more than 400 li long continuous shelter forest system. In more than 2 years, Ji County afforested 300,000 mu, which was 130,000 mu more than the total amount of afforestation done during the previous 30 years. In some places the long-standing vicious cycle began to change.

Leaders Who Vied in Afforestation

The Shanxi Provincial CCP Committee and its members in positions of responsibility attached extreme importance to the building of forestry throughout the province and served as models for CCP committees at all levels. This was another important reason why afforestation of the western mountains went so rapidly. The Provincial CCP Committee and provincial government's principal comrades in charge thoroughgoingly investigated and studied each county, conducted discussions with local county and commune cadres and commune members for further ideasson forestry construction, and worked out with comrades in forestry departments long-range plans and specific measures to be taken for forestry development. Because leaders in the Provincial CCP Committee and Provincial People's Government had thoroughly explored realities in the western mountain region, the several documents, regulations and methods formulated in the province on forestry production accorded rather well with realities and played a constructive role in consolidating mountain rights, forest rights and implementation of forestry production responsibility systems. Most personnel in charge and cadres in provincial forestry departments practiced what they preached and persevered in giving tailored guidance. Provincial Forestry Department director, Liu Qingquan [0491 3237 3123] had served as County CCP Committee secretary during the 1950's and 1960's in Xia and Ji counties. He loved forestry dearly and was known throughout the province as "the afforestation secretary." Wherever he went he did afforestation with the masses. That Xia and Ji counties have been able to become advanced counties in forestries is partially attributable to his efforts. Competition throughout the province and in the western mountain region for leadership in afforestation is becoming greater and greater. Counties, communes, brigades and forestry units in the western mountain region that have received commendations and awards during the past 2 or 3 years total 278, with 107 model workers. At a provincial forestry awards conference held in June 1981, 63 counties, communes, brigades and forest farms in the western mountain region received rewards, and 36 cadres from various levels and commune members were designated provincial forestry models. Those commended as forestry models included Youyu County CCP Committee secretary, Chang Lu [1603 4389]; Ji County CCP Committee secretary, An Kang [1344 1660]; Shenchi County CCP Committee secretary Wang Juqing [3769 5112 3237]; Xing County CCP Committee secretary, Bai Shan [4101 0810]; and Pianguan County CCP Committee secretary Zhang Shiquan [1728 0013 0356] as well as cadres in charge at 15 communes. These comrades were designated afforestation secretaries, but the county magistrate, chairman and the masses extolled them as "people who put down roots." Now the planting of trees for afforestation and the creation of wealth for posterity has become a genuine activity for the broad masses of cadres in the western mountain region. The greening of the motherland with such a group of cadres in its vanguard has spurred on the multitude to mass action for a solid job of afforestation. The barren desertlands and the exhausted valleys and ravines depleted of water have become a moving vista of green mountains, running water, luxuriant forests and abundant grain. What is the future outlook for the loess highlands? The people can take hope from looking at this.

BRIEFS

COTTON EXPERIMENT--This year, the No 148 farm of the 8th Agricultural Division of the Xinjiang Production and Construction Corps has continued to conduct cooperative experiment in ginned cotton with the Namoi Cotton Cooperative in Australia, the (Hefanbao) Economic Company in the United States and the Hong Kong International Cotton Company, Limited. Over the past 2 years, the farm has achieved satisfactory results in conducting cooperative experiments in ginned cotton with foreign countries. This year, they have decided to expand the areas for cooperative experiments to some 6,800 mu, 10 times larger than in 1980. Of the 6,800 mu, some 6,000 mu is economic farmland, the main objective of which is to increase production and economic income while some 500 mu is experimental farmland, the main objective of which is to conduct scientific experiments. By the end of April, all cotton fields had been sown with seeds. Seedlings are now growing well. [HK251425 Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 18 May 82 HK]

CADRES URGED TO PROMOTE DIVERSIFICATION OF ECONOMY

Kunming YUNNAN RIBAO in Chinese 24 Mar 82 p 1

[Artilce by YUNNAN RIBAO contribution commentator: "Take Full Advantage of Superior Local Conditions To Diversify the Economy"]

[Text] Natural resources of various kinds are abundant in our province. During the past few years we have seen some economic factors begin to bring their superiority into play. For example, initial steps have been taken to make tobacco, sugar, tea, rubber and other products our province's "hot-selling" items. It can be said that such "hot-selling" products will have a decisive role to play in developing light industry and foreign trade, and in bringing additional income to the treasury of Yunnan Province. But generally speaking, some economic factors are not yet in a position to demonstrate their superiority. Particularly noteworthy are forestry, animal husbandry, sideline production, and fishery, which remain a weak link to date in the development of the national economy of our province. Although some crop cultivation and breeding businesses such as sericulture, fruit and vegetable farming, hog raising, and poultry egg cultivation have gathered some strength, the pace of their development remains very slow. Also falling below standard is their marketable rate. The output of some products and their purchases remain far from being able to smash their own previous records. For example, in 1981, the output of trefoil rubber, for which Yunnan was named the nation's number one or key producer was only one-sixth of its previous highest output; the output of tea was only 40 jin per unit, down 25 jin from the average national level; the live hog survival rate was only 42 percent, down 20 percent from the national level; the sheep survival rate was only 7 percent; the cattle survival rate was only 3 percent, below the national level of 6 percent. Steps must be taken to change this situation. Beginning this year, we must vigorously devote our energy to overcoming these weaknesses in the midst of the superior economic factors in our province.

In terms of our guiding ideology, developing superior economic factors naturally means efforts to develop projects capable of yielding returns in a short period. At the same time, we must consider things from a long-range strategic point of view, coordinate short-term projects with long-range plans, and back up long-range developments with short-term arrangements. Not only we must fully tap the potential of existing farmland, but we must also envision the development of the entire province. Yunnan is a mountainous province Of its entire land area, 6 percent is irrigated zone, and 94 percent is mountains. Except for craggy terrain, over 80 percent of the province can be covered by trees. The province now has 170 million mu of wasteland which are suited to tree growth, 90 million mu of land now either barren or sparsely planted with trees, 4.2 million mu of water-covered areas. It potential of developing forestry, animal husbandry, fishery, and sideline production is very great. From the long-range point of view, we must gradually begin to shift the emphasis of our work to the diversification of the economy through development of the mountainous areas, waterways, tidal land, grassy slopeland, cropping and breeding farms operated by collectives and families.

The forestry resources in our province are abundant. But the prolonged delay in seeking good answers to some problems concerning policy has caused serious damage to the resources. The destruction of ofrests in some localities has resulted in serious losses of water and soil erosion. The disappearance of this superior economic factor that can be demonstrated through the development of forestry has dried up water for crops and domestic animals, and has even caused shortages of drinking water for people.

We must remember this as a profound lesson. Although much remains to be done in order to bring the superiority of forestry into play, a primary task now facing us is to uphold the principle of forest management as a matter of prime importance, and to display determination to correct problems caused by those who emphasize only logging instead of reforestation and management, and who go on logging without authorization. A look at the current situation suggests that swift action must be taken to enforce the "three-quota system" as a key step in seeking solutions to these problems.

Second, vigorous efforts must be made to promote the production of forest products and byproducts through the successful multipurpose utilization of forest land. Although Yunnan pine and Simao pine abound here, in 1981 we produced only 8,200 tons of surpentine, equal only to 3.7 percent of this available resource. As long as party committees at all levels can effectively strengthen their leadership and take effective measures to tap this superior potential of surpentine production, greater results can be expected in the near future. If we will promise to protect this natural resource from destruction and do everything possible to accelerate the development of turpentine, all existing processing plants can be expected to operate at full capacity within a couple of years. During the past several years, we have witnessed a sharp drop in the output of trefoil rubber. We must conscientiously sum up our experience and lessons in this respect so that we can increase rubber production in the near future. Among other useful forest byproducts are arbutus and olive tree skins, raw materials that can be used to produce adhesives that are essential to the processing of high-quality leather products. In short, the prospect of the multipurpose utilization of forest products and byproducts is bright. This year, vigorous efforts must be made to tap this hitherto untapped potential.

Furthermore, vigorous efforts must be made to promote tea production. The moderate precipitation, climate, and soil conditions in our province are favorable to the growth of tea leaves. With the blessing of this abundant natural resource, our province claims a long history of tea farming. Of the 130 counties and municipalities in the province, 120 have grown tea and the plantations now cover nearly 900,000 mu of land. In 1981, their gross output of tea was 380,000 dan. Yunnan tea is a "hot-selling" item at home and abroad, an important contribution to the province's economic income. Although tea is already a "hot-selling" product in this province, its potential still needs to be tapped. At present, the tea growers in this province face the following problems of major concern: 1) many of their tea plantations are old-fashioned, and are plagued by a lack of ponds; 2) their management is poorly and loosely organized, and their per-unit output remains very low; 3) efforts need to be made to speed up the development of new tea plantations. Because no efforts have been made to break through this sluggish state of tea production, the gross output of Yunnan tea is now ranked seventh, down from fourth on the list of the nation's tea producers. In order to change this situation as quickly as possible, we must make vigorous efforts to transform the low-yielding tea plantations, put into effect the responsibility system, strengthen the management, and strive to increase the per-unit output of tea to nearly 60 jin in the next 2 or 3 years. This means that the potential of the old-fashioned tea plantations can be strongly tapped through transforming them. In the course of transformation the low-yielding tea plantations, the state, collectives and individuals must work together to develop the new tea plantations vigorously.

Although animal husbandry is another superior potential to be tapped in our province, it is also a weak link in the economy. At present, the main problem is the low livestock survival rate and low marketable rate of the meat. Although the reason for the low livestock survival rate is manifold, the main factor stems from our failure to take effective measures to improve the management, scientific breeding techniques, and ventilation of pens. Particularly noteworthy are the high death rates of hogs and chickens, shortages of veterinary teams at basic levels, and the deterioration in the immunization service. In the course of developing the animal husbandry, we must grasp the following points well:

1) Quick efforts must be made to restore the veterinary organizations at basic levels, and to help them improve their technical skills, establish a responsibility system and a reasonable compensation system designed to stimulate the enthusiasm of workers and to promote and popularize scientific livestock breeding techniques. 2) We must do a good job of giving domestic animals immunization shots in marketplaces, at communications centers, and along the borders during the spring and autumn seasons. Veterinary teams and the masses must work together to give immunization shots to 70 to 80 percent of the domestic animals this year in an effort to bring the livestock death rate down to the normal level. 3) Vigorous efforts must be made to promote nutriently well-balanced feed. 4) Vigorous efforts must be made to develop professional and full-time livestock breeders. 5) Steps must be taken to build cross-breeding networks; extensive efforts must be made to improve the varieties of domestic animals, and to consolidate the porkling breeding bases of collective ownership. Commune members must be encouraged to raise sows and breeding hogs in an effort to speed up the production of live hogs and to raise the meat growth rate and its marketable rate.

A vast area of this province is covered by water. In this area, nearly 2,596,000 mu of land can be used to raise fish. The aquatic resources are very rich in the province. But the output of fish remains very low, as low as only 5.9 kilograms per mu of land, which is far below the national level of 28.9 kilograms. In 1980, the distribution of fish was only 0.51 kilogram per person, an amount that fell far short of the people's needs. This problem needs to be solved. At present, the important task is to list the development of fishery as an important item on our agenda, to overcome the "leftist" influence, and to prevent the tendency of catching fish without control and authorization. In the course of actively adjusting, reorganizing and consolidating the fishing operations, we must take resolute measures to protect the aquatic resources, put into effect the fishery policy, and establish and improve the organization of management. Meanwhile, we must institute and improve the responsibility system. Under the principle of facilitating the development of production and the management of fish raising, we can award contracts for fishing raising to professional teams (groups) or individuals. We can also allow them to raise and produce specific amounts of fish from ponds (depending on their size), or award them similar contracts through open bids. Such contracts should be valid for years, and should not be subjected to changes before their expiration date. Furthermore, we must do a good job of scientific research and of selecting and breeding good varieties.

As for those commodities now in short supply at home and abroad, including silk, tung oil, raw lacquer, coffee, spices, strawberrys, star aniseed, udo, southern medical herbs, edible fungi, walnuts, mushrooms, and bamboo shoots, we can take the initiative to develop them in a way that takes into consideration the local conditions. We must strive to overcome the tendency of emphasizing big and neglecting small, of emphasizing "watermelon" and neglecting "sesame," of being unwilling to begin with a small project at a time when we do not have adequate capital to launch ambitious projects. We must broaden the prospect of production from a realistic point of view. In the course of directing production, we must devote our attention to closely coordinating mass production with small-scale production under overall planning and reasonable arrangements. In a special pledge to serve the needs of cities and factories, those living on the outskirts of cities must actively strive to develop the production of vegetables, fruit, poultry eggs, and meat. Our province enjoys a broad prospect for developing agricultural products and byproducts processing enterprises, and we must actively strive to develop them. First, active efforts must be made to develop the processing of agricultural products and byproducts on the spot and to develop a process of selecting products and their multipurpose utilization, in connection with the efforts to develop superior products. Second, in accordance with the principle of economic return on investment and in pursuit of a guarantee to provide the state-owned processing enterprises with sufficient raw materials, the local processors must work out plans on the basis of the availability of raw materials and technical equipment and of the marketing survey of products, and specify the division of responsibility reasonably so that they can avoid losses caused by blind development. Third, attention must be paid to improving the processing technology and quality of products. Fourth, successful efforts must be made to consolidate the existing enterprises operated by communes and brigades.

In the course of diversifying the economy, we may encounter many problems involving industry, commerce, finance, banking, communications and other sectors of the economy. We must effectively strengthen the leadership of party committees and governments at all levels and consider it very important to bear the overall situation in mind. We must also concentrate on grasping the following points well:

First, we must do a good job of implementing the policy and plans for production. In doing so, we must work out a guiding principle and uphold the policy of supplementing the planned economy with marketing surveys: 1) we must extensively educate peasants in "three considerations"; 2) we must widely put into effect the economic contractual system; 3) we must consider administrative intervention, if necessary.

Second, vigorous efforts must be made to establish and improve the responsibility system of economic diversification and to raise the levels of science and technology. Under the responsiblity system of economic diversification, unified management must be emphasized, and contracts based on the needs of various economic operations can be awarded to various professional teams, households, and individual workers for the purpose of facilitating the development of commodity production. Various localities must sum up and exchange their experiences in this respect. Since the responsibility system was put into effect, the vast numbers of cadres and people in the countryside have expressed a strong desire to study science and its application. The leading bodies at all levels must concentrate on promoting agricultural science and technology with the same determination and courage they have displayed in the implementation of policies and the responsibility system. To meet the needs for diversification of the economy, they must concentrate on grasping the following tasks well: 1) They must step up the training of specialized personnel and technicians, and must build and strengthen the contingents of scientists and technicians at the basic level, so that our scientific and technological institutions at all levels can be established and perfected step by step. 2) They must make vigorous efforts to disseminate current achievements in science and technology, and pay attention to coordinating the application of the traditional agricultural experience with that of modern science and technology. 3) They must widely put into practice the joint production responsibility system associated with science and technology, and forge a tie between scientific research and production. 4) Agricultural research units at all levels must organize scientific research in a way designed to tackle certain technical difficulties.

Third, in addition to concentrating on implementing principles and policies and on promoting science and technology, leading cadres at all levels must learn to operate and manage enterprises, learn to do business until they become skilled in economic work, and gradually rid themselves of the manners of "country bumpkins."

Fourth, efforts must be made to speed up the circulation of commodities in the countryside.

Fifth, strengthening leadership over the development of the diversified economy is a problem that needs to be solved by the organizations concerned.

Every plan needs to be implemented by man. Otherwise, all principles, policies, and methods, no matter how perfect, will become empty talk, if they are not put into practice by people. For this reason, departments concerned with economic diversification at all levels must organize people to go to the frontline of production to help the grassroots units effectively solve problems and carry out measures. They must act immediately in order to score new successes in diversifying the economy this year.

POINTERS GIVEN FOR CONSISTENTLY HIGH COTTON YIELDS

Hangzhou ZHEJIANG RIBAO in Chinese 21 Mar 82 p 2

[Article by Chen Qiqing [7115 1142 3237], Shi Cunhao [2457 1317 6964], and Shao Xiaozheng [6730 2551 1767]: "Recognize Objective Realities To Win High Cotton Yields"]

[Text] Zhejiang Province's cotton production has revived and developed during the past several years, but development has not been fast. Last year, in particular, the extent of decline in output was fairly large, arousing concern in all quarters. Among some cadres and the masses there has been a certain amount of discussion as to whether Zhejiang Province is suitable for the growing of cotton and whether high yields can be realized, and there have been fears of difficulty in growing cotton. Recently we made a special investigation and study of this problem.

Zhejiang Province is one of the major cotton producing provinces in the country. It has a long history of cotton growing, and the masses have abundant experience in it. Since the founding of the People's Republic, the province's cotton production has grown very greatly under the leadership of the party, and output has increased severalfold. In 1949, the province's ginned cotton yields averaged 12 jin per mu. In 1964, this increased to 107 jin, making Zhejiang the first "Program" province for cotton in the country. In 1968, the maximum year, yields reached 138 jin per mu. In Ciqi County, more than 400,000 mu of cotton averaged yields of somewhat more than 150 jin per mu, and there were some communes and farms that had yields of more than 200 jin per mu. Ciqi's experiences in growing cotton were spread and extended to numerous cotton growing areas, and the footprints of cotton farmers extended over more than 10 fraternal provinces and municipalities. While he was alive, Premier Zhou was extremely attentive to Zhejiang's cotton production, and he placed a very high value on Ciqi County's experience with high cotton yields. In 1980, despite fairly severe natural disasters, yields continued at 103 jin per mu, making Zhejiang the country's province with the highest yields. Although the province's overall cotton output declined considerably in 1981; nevertheless, in this year of disaster 9 counties and 108 communes had ginned cotton yields of more than 100 jin per mu. The foregoing facts show that Zhejiang Province's cotton growing areas are suited to the growing of cotton, and are capable of high yields.

In that case, what are the problems that impair the province's production of cotton, and given the province's objective realities, what key measures have to be adopted in order to realize consistently high yields?

1. Accurate Understanding of the Province's Climatic Characteristics, Playing Up Strengths and Playing Down Weaknesses To Achieve Early Seedlings, Early Development, and Early Ripening. Climatic conditions in Zhejiang Province both provide many advantages for cotton production, such as a long frost-free period, fairly high temperatures, and ample amount of heat, and also contain some disadvantageous factors, such as the plum rains of the springtime, and notably the typhoons and autumn rains at the end of the season, which greatly hurt consistently high cotton yields. In 6 of the 32 years since Liberation, typhoons caused fairly severe damage to the cotton crops, and in these 6 years, cotton yields averaged 66.8 jin per mu. Flooding caused by rain (the plum rains of spring and the autumn rains) caused fairly severe losses to cotton crops in 11 years; yields averaged 66.5 jin per mu then. Zhejiang Province experiences typhoons frequently, most of them occurring in August. Destructive typhoons are particularly likely to occur after mid-August. Twenty-six years of meteorological data show that autumn rains occurred in late August in 20 years. Therefore, in order to get consistently high cotton yields in Zhejiang Province, it is necessary to play up strengths and play down weaknesses, to guard against disasters and to combat disasters, earliness being the most important thing for the practice of the "three earlys." Early seedlings are the basis; early development is the key; and early ripening is the assurance. This is to say that the optimum flowering and boll-formation period for cotton must be taken firmly in hand to achieve early formation and much formation of summer bolls before 15 August avoiding, insofar as possible, the "August havoc," and the "September rot" typhoons, and disastrous autumn rains. Whenever this can be done, consistently high yields can be realized. Last year, Taohua Commune on a sea island in Putuo County had typhoon disasters that were much more severe than in other cotton growing areas; nevertheless, from the somewhat more than 4,000 mu of cotton in the commune, yields amounted to 138 jin per mu, both yields per unit of area and total output reaching all-time highs. It was the word "early" that underlay this very important experience of this commune, making possible sturdy seedlings that developed early, and summer bolls that carried the day.
